

the right-hand side of the equation is zero. This is the case for the first term, which is proportional to $\epsilon_{\alpha}^{\beta} \partial_{\beta} u_{\alpha}$. For the second term, we have

$$\epsilon_{\alpha}^{\beta} \partial_{\beta} u_{\alpha} = \epsilon_{\alpha}^{\beta} (\partial_{\beta} u_{\alpha}) + u_{\alpha} (\partial_{\beta} \epsilon_{\alpha}^{\beta})$$

and

$$\epsilon_{\alpha}^{\beta} (\partial_{\beta} u_{\alpha}) = \epsilon_{\alpha}^{\beta} \partial_{\beta} u_{\alpha}$$

so

$$\epsilon_{\alpha}^{\beta} \partial_{\beta} u_{\alpha} = \epsilon_{\alpha}^{\beta} \partial_{\beta} u_{\alpha} + u_{\alpha} (\partial_{\beta} \epsilon_{\alpha}^{\beta})$$

which is zero if $\partial_{\beta} \epsilon_{\alpha}^{\beta} = 0$.

Thus, the left-hand side of the equation is zero, so the right-hand side must also be zero.

The present series, entitled "Smithsonian Miscellaneous Collections," is intended to embrace all the publications issued directly by the Smithsonian Institution in octavo form; those in quarto constituting the "Smithsonian Contributions to Knowledge." The quarto series includes memoirs, embracing the records of extended original investigations and researches, resulting in what are believed to be new truths, and constituting positive additions to the sum of human knowledge. The octavo series is designed to contain reports on the present state of our knowledge of particular branches of science; instructions for collecting and digesting facts and materials for research; lists and synopses of species of the organic and inorganic world; museum catalogues; reports of explorations; aids to bibliographical investigations, etc., generally prepared at the express request of the Institution, and at its expense.

In the Smithsonian Contributions to Knowledge, as well as in the present series, each article is separately paged and indexed, and the actual date of its publication is that given on its special title-page, and not that of the volume in which it is placed. In many cases works have been published and largely distributed, years before their combination into volumes.

RESEARCHES ON THE ATTAINMENT OF VERY LOW TEMPERATURES.*

BY MORRIS W. TRAVERS, D.Sc.,

ASSISTANT PROFESSOR OF CHEMISTRY, AND FELLOW OF UNIVERSITY COLLEGE, LONDON, ENGLAND.

PART I.

I. INTRODUCTION.

The following is an account of a series of experiments which originated in the year 1900 in an attempt to obtain a small quantity of liquid hydrogen, to be used in separating the gas neon from helium and argon, with which neon is associated in atmospheric air. Sir William Ramsay and I had, at that time, succeeded in separating the gases argon, krypton and xenon from one another, by condensing mixtures containing them in bulbs cooled in liquid air, and submitting the solid or liquid to fractional distillation. This method could not, however, be applied to the separation of neon; for, as subsequent experiment has proved, the critical point of this gas lies below 65° abs., and consequently it could not be condensed at the temperature of liquid air. It was obvious that unless liquid hydrogen could be obtained, and applied to the separation of the neon from its companions, it would be impossible to obtain the gas in a pure state, and the work on the inactive gases would remain incomplete.

Experiments on the liquefaction of hydrogen were commenced in March, 1900. After some six or eight failures, mainly the results of attempts to adapt an old air liquefier to the new purpose, I devised and constructed an apparatus with which I was able to obtain the necessary quantity of liquid. The work was brought to a successful conclusion on July 6 of that year, and the separation of the pure neon was effected.

During the years 1901 and 1902 I was engaged, with the assistance of Mr. George Senter and Dr. Adrien Jaqueroz, in making accurate measurements of the pressure-coefficients of hydrogen and helium, and in comparing the constant-volume hydrogen and helium thermometers over wide ranges of temperature. This investigation involved the measurement of the vapor-pressures of liquid oxygen and of liquid

* The researches described by Doctor Travers were carried on with the aid of a grant from the Hodgkins Fund of the Smithsonian Institution. It is expected that further researches by Doctor Travers will be published as Part II.

hydrogen at temperatures on the scales of the two thermometers, corresponding to pressures below 800 millimeters of mercury. The liquid hydrogen employed in the researches was obtained by means of the apparatus already referred to. For this purpose, however, it was modified in some details so as to render the production of liquid hydrogen a matter of certainty. Indeed, eight out of nine experiments carried out during the summer of 1902 were successful; the one failure being due to the breaking down of the compressor. The results of these investigations have been published in the *Philosophical Transactions of the Royal Society*.

On concluding this work I turned my attention to the improvement of the apparatus for liquefying hydrogen, and to the theoretical investigation of the processes involved. An account of this work is contained in the following pages.

II. HISTORICAL.

The researches of numerous investigators, notably those of Faraday and Thilorier, carried out during the early part of the last century, had resulted in the liquefaction of all the gases then known, with the exception of hydrogen, nitrogen, oxygen, carbon monoxide, nitric oxide, and methane, which hence received the name of permanent gases. Though Faraday had probably some conception of the explanation of their behavior, it was undoubtedly a matter of general opinion that the gases possessed in themselves a permanent character, or that they would ultimately liquefy were the pressure on them sufficient. It was not until 1869, when Andrews proved there is for each substance a critical temperature above which the liquid and vapor cannot be differentiated, that existence of permanent gases was explained.

No further advance towards the liquefaction of the permanent gases was made till 1877 when, on December 24, communications were received by the French Academy independently from M. Raoul Pictet of Geneva and from M. Louis Cailletet of Chatillon-sur-Seine, announcing the liquefaction of oxygen. A week later M. Cailletet described to the academy some experiments in which, by the process of compression and subsequent expansion of hydrogen, he had succeeded in producing in it a mist, presumably of liquid.

The following is transcribed from the paper which appeared in the *Comptes Rendus* (1877, 85, 1270) :

“ Dans mes premiers essais, je n'avais rien reconnu de particulier ; mais, comme il arrive souvent dans les sciences expérimentales, l'habitude d'observer les phénomènes finit par en faire reconnaître les signes dans les conditions où ils avaient d'abord passé inaperçus.

“ C'est ce qui arrive pour l'hydrogène. En répétant aujourd'hui même, en présence de MM. Berthelot, H. Sainte-Claire Deville et

Mascart, qui veulent bien m'autoriser à invoquer leur témoignage j'ai réussi à observer des indices de liquéfaction de l'hydrogène, dans les conditions d'évidence qui n'ont paru douteuses à aucun des savants témoins de l'expérience. Celle-ci a été répétée un grand nombre de fois. En opérant avec de l'hydrogène pur comprimé vers 280 atmosphères, puis brusquement détendu, nous avons vu se former un brouillard excessivement fin et subtil, suspendu dans toute la longueur du gaz et qui disparaissait subitement. La production même de ce brouillard, malgré son extrême subtilité, a paru incontestable à tous les savants. . . ."

In the light of our present knowledge of the properties of liquid hydrogen some other explanation must be given to the phenomenon observed by M. Cailletet and his colleagues. Possibly the mist was caused by the condensation of some impurity in the hydrogen.

Next year M. Pictet published a similar statement.* Hydrogen was generated by heating potassium formate with caustic potash in a closed apparatus connected with a steel tube terminating in a stopcock. When the pressure had risen to 650 atmospheres, and the tube was cooled to about — 140°C., the cock was opened. The jet of hydrogen issuing from the cock appeared steel-blue in color, and opaque for a length of twelve centimeters. The substance forming the jet struck the ground with a sound like that of hail falling on the earth. It is probable that the explanation of the phenomenon lies in the formation of carbon monoxide and carbon dioxide by the decomposition of the sodium formate.

The earliest experiments leading to results which can in any way be considered as reliable are those of the Polish chemists Wroblewski and Olszewski, which were commenced in 1882, and were carried out partly in conjunction, partly independently, during the succeeding years. That the work presented great difficulties may be imagined when we read of six cubic centimeters of liquid air referred to as "a large quantity."

The earlier experiments, described in letters to the Cracow Academy and in communications to the French Academy, are probably of little direct value, except in so far as they show the efforts which were being made. The following is an extract from one of Wroblewski's papers:[†]

"L'hydrogène soumis à la pression de 180 atm. jusqu'à 100 atm. refroidi par l'azote bouillant dans le vide (à la température de sa solidification) et détendu brusquement sous la pression atmosphérique présente une mousse bien visible. De la couleur grise de cette mousse, où l'œil ne peut distinguer des grouttelettes incolorés, on ne peut pas encore deviner quelle apparence aurait l'hydrogène à l'état de liquide

* Comptes Rendus, 86, 106.

† Comptes Rendus, 1885, 100, 981.

statique et l'on est encore moins autorisé à préciser s'il a ou non une apparence métallique.

"J'ai pu placer dans cette mousse ma pile thermo-électrique et j'ai obtenu suivant les pressions employées des températures de — 208° jusqu'à — 211°C."

The last statement shows clearly that little weight can be attached to these experiments.

Professor Wroblewski's more important work consisted in an investigation of the isothermals of hydrogen at low temperatures, undertaken with a view to the calculation of the critical constants. In this work he was engaged at the time of his death, which occurred in 1888 through an accident with a paraffin lamp. The results were fortunately ready for publication, and appeared shortly afterwards in the *Sitzungsberichte* of the Vienna Academy (October 25, 1888). The following values for the critical constant were calculated by means of an equation of the "Clausius" form:

Critical temperature.....	— 240.4° C.
Critical pressure	— 13.3 atm.
Critical volume	0.00335 c.c.

An exhaustive account of Professor Olszewski's later experiments on the liquefaction of hydrogen has been published by him in the *Philosophical Magazine* for 1895.* The paper also contains a general account of his researches on liquefied gases. The following is an account of his attempt to liquefy hydrogen.

Pure hydrogen was compressed into a glass tube 11 mm. in external diameter and 7 mm. in internal diameter, containing a very thin-walled glass tube, 6 mm. in diameter, to isolate the hydrogen from the warmer walls of the larger tube. The apparatus was cooled with liquid air boiling under less than 10 millimeters pressure. The remaining operations are described by the author in the following words:

"I introduced hydrogen into the tube by slowly opening the cock on the cylinder (which contained pure hydrogen under pressure) till the pressure rose to 140 atmospheres. When the hydrogen in the tube had come down to the temperature of the cooling agent, I little by little produced expansion by opening the screw-cock. The phenomenon of hydrogen ebullition, which was then observed, was much more marked and much longer than during my former investigations in the same direction. But even then I could not perceive any meniscus of liquid hydrogen.

"I have remarked in these experiments that with a slow expansion the phenomenon of sudden ebullition always appears under the same pressure, no matter how great the initial pressure may be, provided

* Vol. 39, p. 188.

that value be not too low. So that by expansions made, beginning with the pressures of 80, 90, 100, 110, 120, 130, 140 atm., the phenomenon described constantly appeared at 20 atm.; but if the initial pressure was 70, 60 and 50 atm., the ebullition appeared at a lower and lower pressure. . . .

"To ascertain the truth of this statement I performed two series of analogous experiments with gases, the critical pressures and temperatures of which are accurately known, viz., with oxygen and ethylene. The critical temperature of oxygen is, according to my former researches, —118.8° and its critical pressure is 50.8 atm. In the same apparatus which I used for the experiments with hydrogen I cooled oxygen by means of ethylene boiling under atmospheric pressure . . . and subjected it to slow expansion beginning with initial pressures, from 40 atm., up to 100 atm. The ebullition of oxygen always appeared at a pressure of about 51 atm., provided the initial pressure was not lower than 80 atm. . . .

"I made similar experiments with ethylene, using the apparatus of Cailletet. . . ."

These experiments confirmed those made with oxygen, indicating that this "dynamical method" is applicable to the determination of critical pressures, though it would only be employed in cases, like that of hydrogen, when no other course was possible.

The next paper published in the same year* describes the application of these results to the determination of the critical and boiling temperatures of hydrogen. In place of the glass compression tube a steel vessel containing a very thin-walled glass tube was employed, the whole enclosing a resistance thermometer consisting of a very fine wire of pure platinum wound on a frame of thin mica. The wire had a diameter of 0.06 mm.; its resistance was determined at the following temperatures:

Temperature.	Resistance.
0°	1,000 ohms.
— 78.2°	800 "
— 182.5°	523 "
— 208.3°	453 "

The hydrogen was compressed into the steel apparatus, which was cooled as in the previous experiment in liquid oxygen boiling under a pressure of 15 mm., and the expansion was carried out in the usual manner. The resistance of the coil was measured by means of a Wheatstone bridge and reflecting galvanometer, and resistance in the opposite arms of the balance was repeatedly adjusted, till on making the expansion no deflection of the galvanometer was observed. The following results were obtained:

* Philosophical Magazine, 40, 202.

Hydrogen Expanded to 20 atmospheres.	Resistance of Coils. 383 ohms.	Temperatures. —234.5° Centigrade.
10 "	369 "	—239.7 "
1 atmosphere.	359 "	—243.5 "

The temperature in the last column was calculated by linear extrapolation from the resistance of the coil at temperatures corresponding to —182.5°C. and —208.5°C.

According to Dewar, though the method by which the measurements were made has not been published, the critical temperature of hydrogen is about —244°C., and the critical pressure less than 15 atmospheres. The boiling point of hydrogen according to Travers and Jaquerod* is 20.55° on the helium scale and 20.36° on the hydrogen scale. Callendar† has pointed out the recalculation of Olszewski's results by means of his difference formula leads to the conclusion that the temperatures are about one degree higher than those given above; at the same time it is possible that the platinum thermometer may behave erratically at low temperatures. This latter view is confirmed by Dewar,‡ who obtained —243.6° and —237.9° for the boiling point of hydrogen on two platinum thermometers; one of these values is almost identical with that obtained by Olszewski.

These facts may be taken as sufficient evidence that Olszewski obtained liquid hydrogen, first in the form of a mist or spray in a glass tube, and afterwards in a steel vessel. In the latter experiment it is probable that the liquid at its boiling point persisted for a sufficient time to cool a platinum resistance thermometer to that temperature.

III. THEORETICAL DISCUSSION OF THE FOREGOING.

In discussing the principles on which the experiments of Cailletet, Pictet, Wroblewski and Olszewski on the one hand, and of Dewar and myself on the other hand, considerable confusion has arisen. Indeed several well-known text-books of physics, and even certain works devoted to the study of liquefied gases, attribute the cooling which takes place in every case to adiabatic expansion. Dewar's early papers make no mention of the fact that in his, as in my own experiments, the cooling is due to the fact that when hydrogen is cooled to the temperature of liquid air it, like air or carbonic acid, becomes cooled when allowed to expand without performing external work. The cooling may be the result of work done against internal forces. This matter is first discussed in my paper on the liquefaction of hydrogen published in 1901.

In the earlier experiments referred to above, the gas was compressed either into a tube over mercury, so that in opening a cock the mercury

* Philosophical Transactions, 1902.

† Philosophical Magazine, 1899, 191.

‡ Bakerian Lecture, 1901.

escaped from the tube as the gas expanded; or the gas was compressed directly by means of a pump into a glass or steel vessel, and then part of it was allowed to escape directly through an orifice. In the first case the gas exerted a pressure on the mercury, and on expanding did work which was performed in giving the mercury a certain velocity through the escape cock, and partly in overcoming fluid friction. In the second case, part of the gas which remained in the vessel did work in driving the remainder through the orifice or cock, partly in overcoming friction at the orifice, partly in giving to the gas an increased velocity, which would quickly be dissipated in the formation of eddy currents outside the orifice.

If we were dealing with a perfect gas for which the simple law

$$pv = \text{const.}$$

were rigidly true, and if such a gas were allowed to expand, or were compressed, adiabatically, the relation between pressure and volume would be expressed by the equation

$$pv^k = \text{const.},$$

where k is the ratio of the specific heat at constant pressure to the specific heat at constant volume. If the gas were allowed to expand adiabatically under the conditions mentioned above, where p_1 and p_2 are the initial and final pressure, and T_1 and T_2 the initial and final absolute temperatures,

$$\frac{T_1}{T_2} = \left(\frac{p_1}{p_2} \right)^{\frac{k-1}{k}}.$$

Since the heat capacity of the gas is always considerably less than that of the vessel in which it is contained, the condition represented above is probably never approached, though, as Olszewski's later experiments show, a considerable degree of cooling can be effected. The practical application of the principle is probably only possible on a large scale.

Olszewski's observation that when the initial pressure in the apparatus exceeded a certain value the liquid always appears when the pressure falls to the critical pressure, is not further discussed by him; the phenomenon can, however, be simply explained by means of an Andrews diagram (fig. 1).

Suppose that the gas is compressed along the isothermal $a - a' - a'' - a'''$, and under the conditions determined by these points is, in successive experiments, allowed to expand adiabatically. In each case liquid should first appear at the point at which the adiabatic cuts the dotted line enclosing the area which represents the conditions under which the

liquid and gaseous phases can connect. The adiabatic $a''' b'''$ passes through the critical point, so that in this case the liquid will first appear at the critical pressure. For higher initial compressions the adiabatics will lie on the left hand side of the critical point on the diagram, and

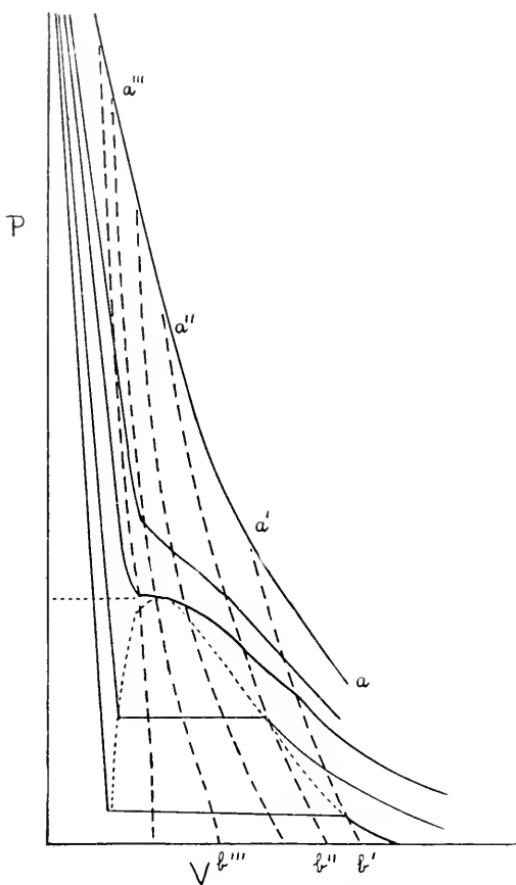

FIG. 1.—Andrews diagram.

liquid will first appear under conditions represented by the point at which they cut the horizontal line drawn through the critical point. For high pressures the adiabatics will, of course, lie very close together, and the horizontal line will differ but slightly from the curve joining the ends of the horizontal section of the isothermal.

IV. THE APPLICATION OF THE JOULE-THOMSON EFFECT TO THE LIQUEFACTION OF AIR.

The change in temperature which takes place when a gas is allowed to expand without performing effective external work was first studied by Joule and Lord Kelvin in 1848. The gas compressed to about two

atmospheres flowed in a steady stream through a plug of compressed fiber so that the increase in the kinetic energy of the gas, which would take place if the gas streamed through an orifice in a plate, was reduced to a minimum, and practically eliminated. In passing from the higher to the lower pressure work was done in overcoming internal friction, so that were the gas a perfect one its total energy content would remain constant, and there would be no change of temperature. In the case of air and carbon dioxide it was found, however, that a fall of temperature took place; hydrogen, on the other hand, became warmer.

The change of temperature must be attributed to the performance of work in overcoming internal stresses; though as to what the nature of these stresses may be we have at present no knowledge. In many text-books of physics it is stated that the direction of the change of temperature, the sign of the Joule-Thomson effect, is connected with the variation of the product " PV " with pressure for the gas. Though for hydrogen (and helium) the value of the product increases with rise of pressure, while it decreases in the case of air and all other gases, this relationship does not really apply. For pressures above fifty atmospheres the value of the product PV for air increases with rise of pressure, yet, if we expand air from 100 atmospheres to 50 atmospheres, it still becomes cooled.

For small differences of pressure the change of temperature was found to be directly proportional to the difference between the pressure on the two sides of the plug. The results are stated by the original investigators in terms of degrees Centigrade per hundred inches of mercury differences of pressure; it is now more usual to express the value of the Joule-Thomson effect in terms of degrees per atmosphere difference of pressure.

The experiments which were carried out at temperatures between the boiling and melting points of water, showed that the magnitude of the effect varied with the temperature, and might be represented by the formula,

$$\chi = \frac{\alpha}{T} \pm \beta,$$

where χ is the Joule-Thomson Effect, T is the absolute temperature and α and β are constants. The values of the constants for air and hydrogen are as follows:

	α	β
Air	64.1	-0.331
Hydrogen	441.5	0.697

These figures indicate that for either gas above a certain temperature, the inversion temperature of the Joule-Thomson effect, the effect

will be positive; below that temperature it will be negative. The inversion points calculated by Witkowski are 633° and 193.7° absolute for air and hydrogen respectively. Olszewski (*Nature*, 1902) confirms the second figure, finding 192.5° absolute for the inversion point for hydrogen. He points out that the inversion points are practically corresponding temperatures for the two gases.

The application of the principle of free expansion to the liquefaction of air was first made practicable by Hampson in England and Linde in Germany. Since Hampson and Linde's work paved the way to the production of liquid hydrogen, by a very similar process, and as my researches have been based upon their results, some mention must be made of their work. To Dr. Hampson I am particularly indebted for much advice and assistance in carrying out my investigations.

V. THE PERFORMANCE OF THE HAMPSON AIR LIQUEFIER.

The Hampson air liquefier is too well known to require a lengthy description. It consists of a coil formed by winding two, or in some cases four, copper tubes coaxially so as to build up a cylinder 100 cm. long and 30 cm. in diameter. The coil is enclosed in a metal case. Air enters the copper tube at the top under a pressure of 180 atmospheres, and expands at a valve, in which the tubes unite at the bottom of the coil. The air, cooled by expansion, presses upwards through the interstices of the coil, cooling the compressed air it contains. The cooling of the valve is therefore progressive, and results, after a few minutes, in the partial liquefaction of the escaping air. The liquid collects in a space at the bottom of the metal case containing the coil, and is drawn off from time to time through a cock.

The apparatus as installed in the Chemical Department of University College, London, is worked in connection with a Whitehead "torpedo compressor" driven by an electro-motor. To deliver about ten cubic meters of air per hour (measured under atmospheric conditions), and to maintain a pressure in the liquefier of 180 atmospheres, requires the expenditure of about 6.5 horse-power; the compressor runs at 360 revolutions per minute. An attempt has been made by Mr. Arnold Ogden and myself to determine the efficiency of the plant. I have also carried out a fairly complete investigation of the air liquefier.

The work done in compressing the air was determined by measuring the electrical energy absorbed by the motor under the following conditions :

Power required to run motor free	0.6	E. H. P.
Power absorbed by motor, belt and bearings (cylinders removed) ..	1.8	"
Power required to run motor with cylinder in place (no compression) ..	3.7	"

Power absorbed during trial.....	(a) 6.4 E. H. P.	(b) 6.2	"
Power absorbed in compressing the air.....	2.7 "	2.5	"
Weight of air compressed per hour.....	14.4 kilos	14.1 kilos	
Weight of air compressed per E. H. P.....	5.3 "	5.6	"
Pressure	165 atm.	163 atm.	
E. H. P. required to compress the same quantity of air isothermally.....	2.23	2.18	

The energy put into the air is thus between 20 and 25 percent more than would be required for isothermal compression. The compression is carried out in two stages, the ratio of the initial to the final pressure being the same in each stage, so that thrusts on the two pistons were balanced. The pressure in the coil and pipe connecting the two cylinders was measured during one of the trials, and was found to vary between thirteen and fourteen atmospheres. In a larger compressor, working at a slower speed, the compression would approach much more closely to the isothermal. The efficiency, which is only about 0.13 in the Whitehead compressor, would also be much higher.

The investigation of the Hampson air liquefier proved somewhat troublesome as many factors had to be taken into consideration. It was necessary to measure:

The total quantity of air passing through the apparatus.

The quantity of liquid air produced.

The rate of absorption of heat by the coil through conduction, in terms of the liquid air evaporated.

The loss, through evaporation, of liquid air on drawing off the liquid from the cock at the bottom of the apparatus.

The pressure and temperature of the air entering and leaving the apparatus.

The temperature of the liquid air.

The total quantity of air passing through the apparatus was measured by connecting the exhaust pipe of the liquefier with a gas meter. This "sixty-light" meter was placed at my disposal by the Gas Light and Coke Company of London: to the manager of the Company I wish to tender my thanks.

The liquid air was drawn off at definite intervals into a weighed globular vacuum vessel, silvered between the walls. The vessel was half full of liquid air at the commencement of each experiment, and the rate at which liquid air evaporated from it was determined.

To measure the quantity of air lost by evaporation of the liquid, as it issued from the cock on the Hampson apparatus, the arrangement shown in fig. 2, A, B, was adopted. The mouth of the vacuum vessel *a* was fitted with a rubber stopper *b*, through which passed a tube *c* of the same diameter as the thumb-screw *f* on the liquid air valve *e* of the Hampson liquefier, with which it was connected by means of a piece

of wide rubber tube. The side tube *d* communicated by means of a flexible rubber tube with a small gasometer.

The vacuum vessel rested on the point at which it was finally sealed (fig. 2, B), so that when the liquid air cock was opened by rotating the

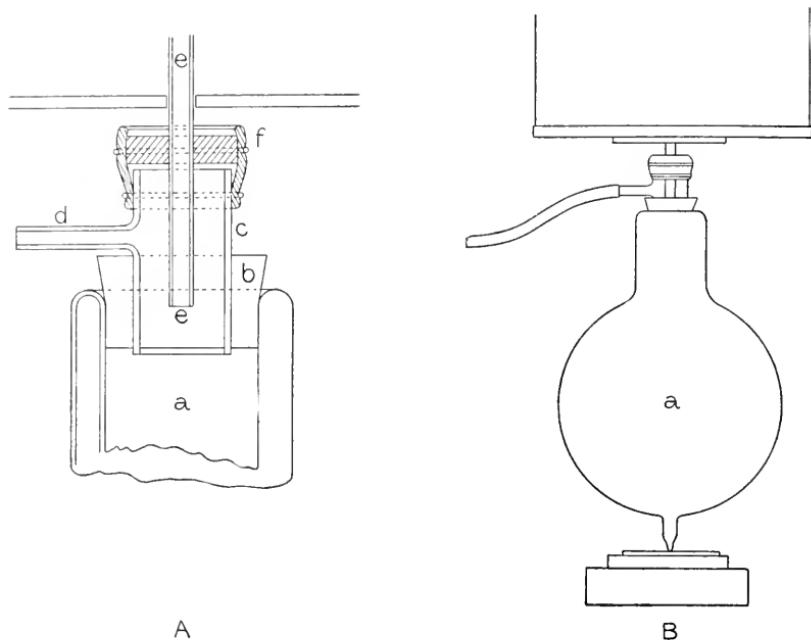

FIG. 2.—Apparatus for measuring air lost by evaporation of liquid.

thumb screw *f*, it merely turned on its axis. The quantity of gaseous air produced by the evaporation of the liquid air could be measured by measuring the rise of the gasometer attached to *d*. The quantity of liquid air collected in the vacuum vessel amounted to about one kilogram per hour; the loss by evaporation corresponding to the same period was usually seventy to eighty grams per hour.

The quantity of heat entering the Hampson apparatus through its insulating packing of animal wool was determined by stopping the compressor when the liquid air in the collecting chamber had been allowed to accumulate for five minutes, closing the expansion valve, allowing the air to escape from the regenerator coil by means of a side-cock *b* outside the apparatus, and measuring the rate of evaporation of the liquid air from the inside of the apparatus, and the rate of change of temperature of the regenerator coil. The latter measurement was made by means of an air thermometer with a narrow cylindrical bulb which was inserted through the center of the coil in place of the valve spindle. The following is a record of the results of an experiment.

Time after Stopping Compressor.	Quantity of Air Collected per Minute.	Mean Temperature of Coil (Absolute).
0		
5	5.2 liters.	257
7	5.2	255
9	4.5	250
11	4.0	244
13	3.7	241
15	3.2	239.5
17	3.2	239
19	2.9	238.5
21	2.9	238.5
22	2.8	239

It will be seen that as soon as the circulation of the air through the apparatus was suspended the liquid air in it began to evaporate rapidly, heat being conveyed to it by conduction from the outside. However, long before the whole of the liquid air in the apparatus had evaporated the temperature of the coils had become steady and the quantity of liquid air thus evaporating per minute could be taken as a measure of the quantity of heat entering the apparatus during the process of liquefying air. This quantity corresponds to about 2.6 liters of gaseous air per minute, or to a loss of 200 grams of liquid air per hour.

During an actual experiment it was the duty of one assistant to maintain a steady current of air, escaping at an almost constant pressure, through the apparatus. The pressure gauges were read every minute; the gas meter readings were taken at the end of every half hour, the liquid air was drawn off every five minutes, and the vacuum vessels removed and weighed every half hour; the temperature at which the air entered and left the apparatus and the barometer readings were taken at intervals during an experiment. The following are the results of some observations:

December 14, 1902. Machine started at 10:20 A. M.

Duration of experiment	10:55 to 11:25	11:25 to 11:55
Weight of liquid air collected.....	460 gms.	490 gms.
Loss by evaporation.....	40 gms.	35 gms.
Loss due to heat absorption by liquefier	100 gms.	100 gms.
Weight of air passing through gas meter	6,620 gms.	6,525 gms.
Total weight of air passing through apparatus	7,120 gms.	7,050 gms.
Theoretical quantity of liquid air per hundred of gaseous air.....	8.4	8.9
Quantity collected per hundred of gaseous air	6.4	6.9
Efficiency of liquefier.....	76.2	77.5
Mean pressure	167 atm.	165 atm.
Temperature interchange.....	0.4° C.	0.4° C.

The results of other sets of observations led to practically the same result. The errors of the various observations probably reduce the

accuracy of the results to within about two percent of the truth. The final result leads to the conclusion that the theoretical quantity of liquid air which it should be possible to obtain by the Hampson-Linde principles, where the air is expanded from 180 atmospheres, is between eight and nine percent of the air passing into the apparatus.

The complete theoretical study of the Hampson-Linde process is impossible, both on account of its highly complicated nature, and of our ignorance of the thermodynamic properties of air over wide ranges of temperature and pressure. The results stated above lead however to conclusions which are interesting and are hardly likely to be merely a matter of chance.

If air were compressed to P atmospheres and allowed to expand, as in the Hampson machine, but so that the current of air did not flow back over the coil, the fall of temperature of the escaping gas at a short distance from the jet could be calculated from the formula

$$\Delta T = z(P - p),$$

and the heat absorbed by

$$\Delta Q = z(P - p)Cp,$$

where z is the Joule-Thomson Effect and Cp is the specific heat at a constant pressure of one atmosphere.

Since the work done on the gas in bringing it toward the jet is practically equal to the work done by the gas in its passage away from the jet pv being very nearly constant, the quantity ΔQ is a measure of the change in the internal energy of the gas in passing from pressure P to pressure p . This being the case it should be possible to pass over intermediate stages to calculate the quantity of liquid air produced in the Hampson apparatus from known data.

The specific heat at a constant pressure of one atmosphere (Cp) has been found by Witkowsky* to have the value of 0.237 between 100°C. and the temperature of liquid air; the same value was obtained by Regnault for the higher range of temperature. The Joule-Thomson effect at 10°, the mean temperature of the air entering the liquefier, was found by Joule and Lord Kelvin to be 0.25°C. per atmosphere. The latent heat of vaporization of air is about 50 cal.

Suppose the air enters the liquefier at 165 atmospheres pressure and at 9.5°C. If x /x of the air liquefies at 87° abs.,

$$\text{Heat absorption on expansion} = 0.25 \times 0.237 \times 164;$$

$$\text{Heat absorption due to cooling and liquefaction of } x \text{ parts of air} \\ = x \{ 50 + (0.237 \times 206) \};$$

$$\text{Heat absorption due to cooling of unliquefied air} = (1 - x) \\ (0.5 \times 0.237).$$

* Philosophical Magazine, July, 1896.

Quantity of air liquefied = 9.5 to 10 percent.

This result is of considerable value in considering the phenomena connected with the liquefaction of hydrogen.

VI. THE LIQUEFACTION OF HYDROGEN. PRELIMINARY EXPERIMENTS.

It has already been pointed out that the original experiments of Joule and Lord Kelvin showed that hydrogen, when allowed to expand freely, behaved differently from other gases, becoming heated instead of cooled. The magnitude of the effect depended upon the absolute temperature at which the experiment was performed, decreasing with fall of temperature. From their experiments it might be predicted that the effect would change sign at very low temperatures. Employing the formula,

$$x = \frac{\alpha}{T} - \beta$$

to represent the experimental results, Witkowski found 64.1 and 0.331 for the values of the constants α and β respectively, and -79°C . for the inversion point of the effect. Witkowski's prediction has recently been verified experimentally by Olszewski (p. 10).

In 1898 Dewar* succeeded in obtaining a jet of hydrogen sufficiently cold to solidify air, and later constructed an apparatus with which he obtained liquid hydrogen in quantity. In his first experiments he compressed the gas into steel cylinders under 180 atmospheres, and then allowed it to pass through coils cooled in solid carbonic acid, and in liquid air boiling under reduced pressure, to a regenerator coil contained within a vacuum vessel. The gas escaped through a pin valve at the bottom of the regenerative coil, and became cooled, but before any liquid could be collected the opening had become blocked with some solid impurity, and the experiment was at an end. Later, Dewar constructed a larger apparatus, and succeeded in obtaining liquid hydrogen in quantity. He has not, however, published any description of it.

Dewar's first experiment had confirmed the prediction that hydrogen, when cooled to the temperature of liquid air, became further cooled on free expansion, but it did not throw any further light on the behavior of this gas. Indeed it still remained possible, though perhaps improbable, that it would only be necessary to cool the gas to the temperature of solid carbonic acid before allowing it to enter the regenerator coil of the liquefaction apparatus. Accordingly some preliminary experiments were set on foot in which a Hampson air liquefier, modified as occasion required, was employed.

* Proceedings Chemical Society.

In my first experiments the hydrogen before entering the regenerator coil of the Hampson apparatus, which was cooled by making liquid air in it, was passed through a coil immersed in solid carbonic acid and alcohol (-78°C .). The result was negative; indeed, it appeared that the temperature of the inside of the apparatus began to rise as soon as the hydrogen was allowed to expand in it, for on opening the liquid air cock at the base of the apparatus the temperature of the gas which escaped ceased after the first few minutes from being extremely cold.

More than two months were spent in similar experiments with like results. If, however, these experiments led to no immediate results, they showed clearly that even though it might be theoretically possible to liquefy hydrogen by the method of free expansion without employing liquid air as a cooling agent, it was practically essential to cool the gas to the lowest attainable temperature before allowing it to expand. This knowledge, and the experience in dealing with compressed hydrogen, gained in the course of these experiments led me to design an apparatus with which I was at once successful in obtaining liquid hydrogen. The apparatus I constructed, with the assistance of Mr. J. Holding, without whom I could not have carried on these researches; it cost but a few shillings, and after being slightly modified it served me again in 1902 in my researches on the properties of liquid hydrogen.

VII. THE FIRST HYDROGEN LIQUEFIER.

This apparatus has been fully described in a paper read before the Physical Society of London in November, 1900.* Fig. 3, A and B, shows the general structure of the apparatus as first used, and the modifications which were introduced into it for my later experiments.

In the original form (A), the hydrogen, under a pressure of from 150 to 180 atmospheres, was first cooled to -75° by passing through a coil *A* immersed in a mixture of solid carbonic acid and alcohol. It then passed through a coil contained within the central chamber *B*, which, during an experiment, was continually replenished with liquid air. The coil passed through the floor of the chamber *B* into a lower chamber *C*, which communicated with an exhaust pump through the pipe *f*. Liquid air was allowed to flow from *B* into *C* through a valve, which was controlled from above by the lever *b*, and evaporating under a pressure of 100 mm. reduced the temperature of the compressed gas to below -200°C .

The gas then entered the regenerator coil *D*, which was much shorter than in the Hampson air liquefier, being 180 mm. long and 50 mm. in diameter. The reason for taking these dimensions will be dealt

* Philosophical Magazine, 1901, p. 411.

with later (Part II). The regenerator coil and the lower part of the chamber *C* were enclosed within the vacuum vessel *H*, which was secured to the metallic part of the apparatus by means of a gland *p* (fig. 4) which compressed a rubber ring into the space between the outer wall

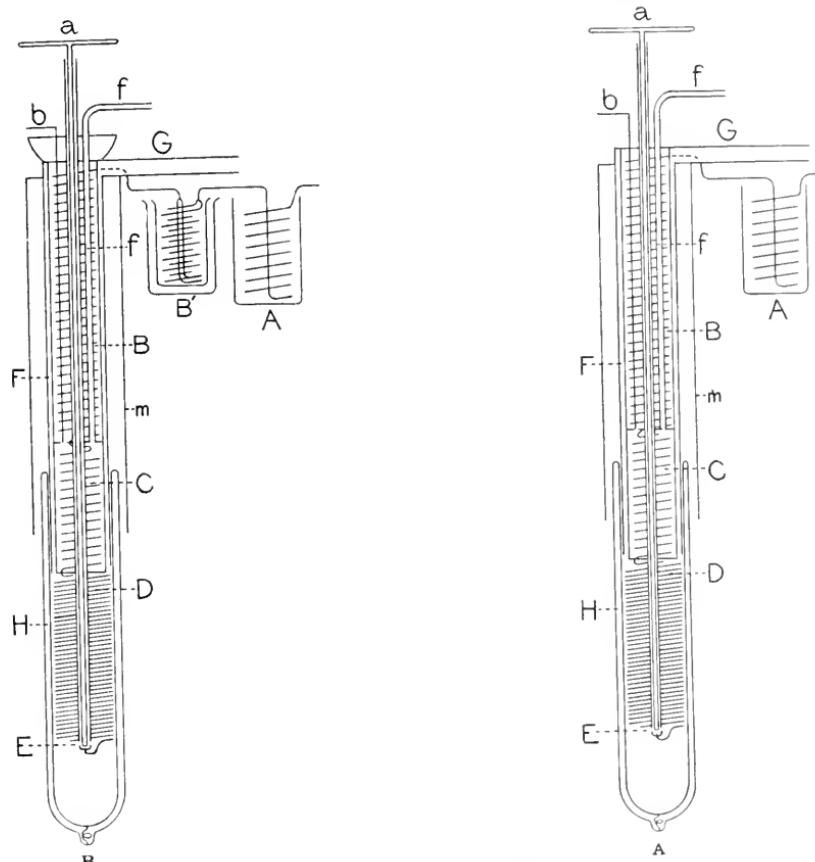

FIG. 3.—Hydrogen liquefier.

of the vacuum vessel and the inner wall of the tube *m*, making a gas-tight junction. The apparatus rested on a brass flange, soldered to the tube *m*, in a round hole in a wooden shelf fixed to the wall of the compressor room. The upper part was surrounded with a thick layer of natural wool.

The hydrogen expanding at the valve *E*, which was controlled by the lever *a*, became further cooled, and passing upward through the interstices of the coil, cooling it and the gas passing through it, so that after a short time liquid began to separate in the vacuum vessel. From the top of the regenerator coil the gas passed through the annular space *F*, surrounding the chambers *B* and *C*, and returned through the tube *G* to the compressor.

The hydrogen which liquefied in *H* was drawn off and collected by the method described on page 20. The arrangements for the compression and circulation of the hydrogen gas will also be dealt with later.

The modifications which were introduced into the apparatus, when I recommenced my experiments in 1902, were simple though important. As originally constructed the coil in the liquid air chamber *B* was so short that it did not present sufficient surface for the effective cooling of the compressed gas passing through it. Further, the chamber *B* was so narrow that not only was it difficult to fill it with liquid air, but if, through irregular adjustment of the valve, there was a sudden rush of gas through the coil, the liquid air boiled violently, and overflowed the chamber.

This difficulty was easily overcome by introducing between *A* and *B* (fig. 3, *B'*) a coil *B'* consisting of two five-meter lengths of copper pipe wound into an open spiral. The pipes were carefully spaced by means of pieces of copper wire soldered to them at intervals. The coil was immersed in liquid air contained in the inner of two glass beakers, which were separated by pieces of cork, so as to leave an air space between them, and surrounded with a thick layer of natural wool.

A copper funnel was also soldered to the top of the tube which formed the chamber *B*, to facilitate the operation of filling it with liquid air. The apparatus as thus modified was used about ten times. Of these experiments only one failed through a break-down in the compressor.

VIII. THE SECOND HYDROGEN LIQUEFIER.

Shortly after I had completed the researches I have just referred to, I was asked by Professor d'Arsonval of Paris, and by Professor Anschütz of Bonn, to design hydrogen liquefiers for their laboratories. As I had not then carried out any further experiments with a view to improving my method of liquefying hydrogen, and as the apparatus I had already constructed had given me perfect satisfaction, except that it was not very economic so far as the refrigerants, liquid air and carbon dioxide, were concerned, I designed another machine of the same principle but of a more compact form. The apparatus was constructed by Brin's Oxygen Company.

A section of the apparatus is shown in fig. 4. The hydrogen from the compressor enters the apparatus at the cross-piece below the pressure gauge and passes first through the coil in the chamber *A*, which is intended to contain a mixture of carbonic acid and alcohol. The whole system of coils is double, each component being of the same length. The total length of copper coil in each of the chambers *A* and *B* is about twenty meters. The cock *x* is intended to allow the hydrogen

to escape and return to the gasometer in case the expansion valve *E* becomes blocked. After passing through *A*, the compressed gas passes through the coils in the chambers *B* and *C*. The chamber *B* contains liquid air, some of which is allowed to flow into *C* through a pin valve which is regulated by the rod *b*. The liquid air in *C* evaporates under a pressure of about 100 millimeters of mercury, an exhaust being maintained by means of a pump communicating with *B* through the tube *f*, and reduces the temperature of the compressed gas to below -200° C. The total length of coil in the chamber *C* is about five meters. The gas then enters the regenerator coil *D*, 180 mm. long and 50 mm. diameter, and passing through it expands at the valve *E*, which is controlled by means of the valve-rod and lever *a*. The expanded gas passes upwards through the interstices of the regenerator coil, and returns by way of the annular space *F* and the tube *G* to the compressor.

The accompanying diagram of this apparatus shows clearly how the gas-tight connection between the outer wal-

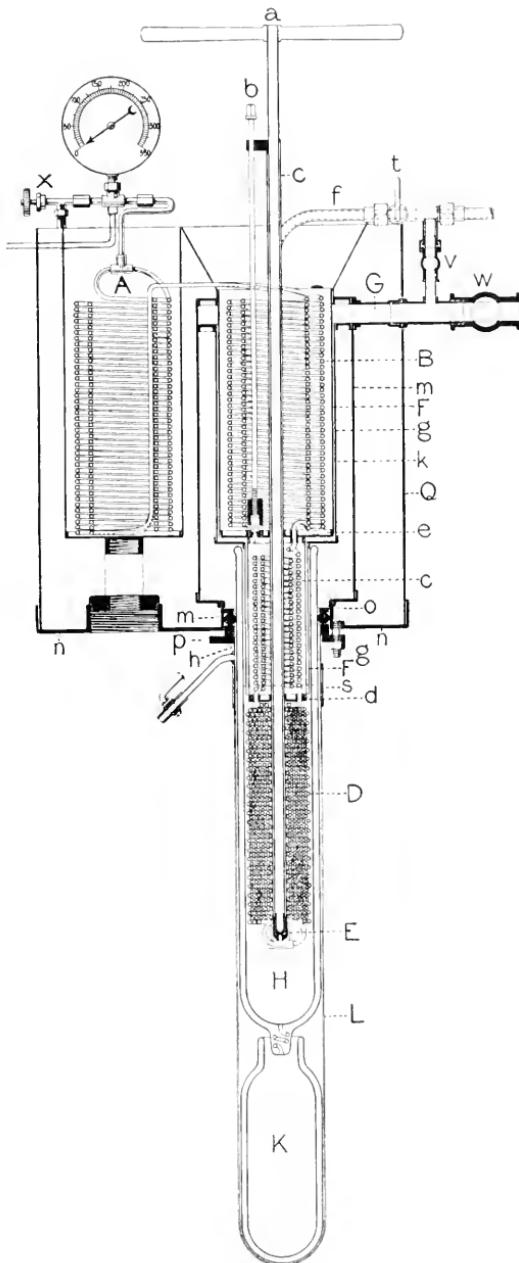

FIG. 4.—Section of hydrogen liquefier.

of the vacuum-vessel *H* and the inner wall of the lower part of the supporting tube *mm* is made. The brass ring *o* is supported above by a slight flange on the inside of the lower portion of the tube *m*, and a rubber ring is compressed between this ring and a gland *p*, which is forced home by means of three screws, of which one is seen in the diagram. As the lower part of the tube *m* is continuous with the brass plate *nn*, it never becomes very cold, and the junction is always gas-tight.

The liquid hydrogen which is formed in the vacuum vessel *H* is collected in the vessel *K*. This vessel is placed inside a tube *L*, which is long enough to enclose *H* as far as the lower edge of the brass tube *h*, which forms part of the gland *p*. A rubber sleeve is secured by wire to *h* and *L* making a gas-tight junction. By opening the tap *r* gas can be allowed to escape from the space within *L*, and consequently liquid can flow from *H* into *K*. This enables one to dispense with a cock at the bottom of the vacuum vessel *H*. By connecting the cock *r* to the supply pipe from the gasometer (fig. 8, *S*), loss of hydrogen can be avoided.

During an experiment, the tube *L* and its contents are enclosed within an arrangement of three concentric glass shades in order to shield off heat, and to prevent the condensation of moisture taking place.

The apparatus is supported on a cast iron stand with a vertical column 130 cm. high, which screws into the bottom of the brass plate *mn*.

This latter is of oval shape and supports a brass case *Q* which surrounds the upper part of the apparatus, the intermediate space being packed with wool.

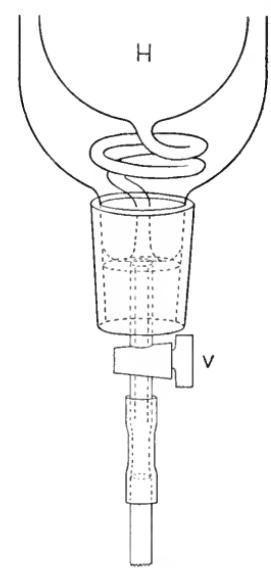

FIG. 5.—Brass tap to vacuum vessel.

The use of the cocks *t*, *v* and *w* must now be pointed out. With this type of liquefier, the first step toward liquefaction of hydrogen is to cool the whole apparatus to the temperature of liquid air. With this object a small brass tap *V* (fig. 5) is fitted by means of a rubber cap to the nozzle of the vacuum vessel *H* and this is in turn connected by a short piece of rubber tube to a glass tube 300 mm. long. By closing the cocks *t* and *w*, opening the cock *V*, and starting the exhaust pump, liquid air can be drawn through the glass tube and the cock *V* into the vacuum vessel *H* from a vacuum vessel, usually containing two liters of the liquid. Liquid air is drawn into the vessel *H* till it rises above the top of the coil *D*; then, by closing the cock *V* and maintaining the exhaust, the temperature of

the coil can be reduced to below -200°C . Meanwhile liquid air is poured into the chamber *B*, and by opening the cock *t* some of it is drawn into the chamber *C*.

IX. HYDROGEN LIQUEFIER WITH SECOND REGENERATOR COIL.

In each of the different forms of the hydrogen liquefier which have hitherto been described there exists one very obvious defect: the hydrogen, after expanding at the valve *E* and passing through the interstices of the regenerator coil *D*, is at a temperature not far from -210°C ., and in this condition it leaves the apparatus, absorbing heat from the walls of the tube through which it passes on its return to the compressor.

Now if we assume that the specific heat of hydrogen at a constant pressure of one atmosphere is equal to 3.41 units over the range of temperature we are considering (see page 14), the heat which each gram of hydrogen would absorb in returning to the normal temperature would be

$$3.41 \times 220 = 750 \text{ units.}$$

As approximately 1,000 grams of hydrogen pass through the apparatus per hour, this involves a loss of 750,000 heat units, the equivalent of fifteen liters of liquid air.

In order to estimate the relative advantage of employing the cold hydrogen in place of solid carbonic acid as a means of cooling the incoming gas, it would be necessary to determine the specific heat of the compressed hydrogen over the range of temperature. The measurements could not, however, be carried out with sufficient accuracy to be of any real value without great difficulty, and, indeed, it would make no appreciable difference were the specific heat of the hydrogen half again as great.

If one assumes that the relationship between the internal energy of the compressed and expanded hydrogen can be calculated, as in the case of air, from the formula (page —),

$$\mathcal{J}Q = K(\mathcal{J}p)Cp,$$

where $\mathcal{J}Q$ is the heat generated or absorbed by the gas during its passage through the regenerator coils of the apparatus, K the Joule-Thomson Effect at which it enters the apparatus, $\mathcal{J}p$ the fall of pressure in the apparatus, and Cp the specific heat of the gas under a constant pressure of one atmosphere.—to cool the gas compressed to 150 atmosphere from 15°C . to -75°C . it is necessary to absorb

$$90 \times 3.41 + 0.09 \times 150 \times 3.41,$$

a quantity ten percent greater than that calculated on the assumption that the thermal capacities of the compressed and expanded hydrogen are the same. This difference is insignificant and has no effect on the general problem.

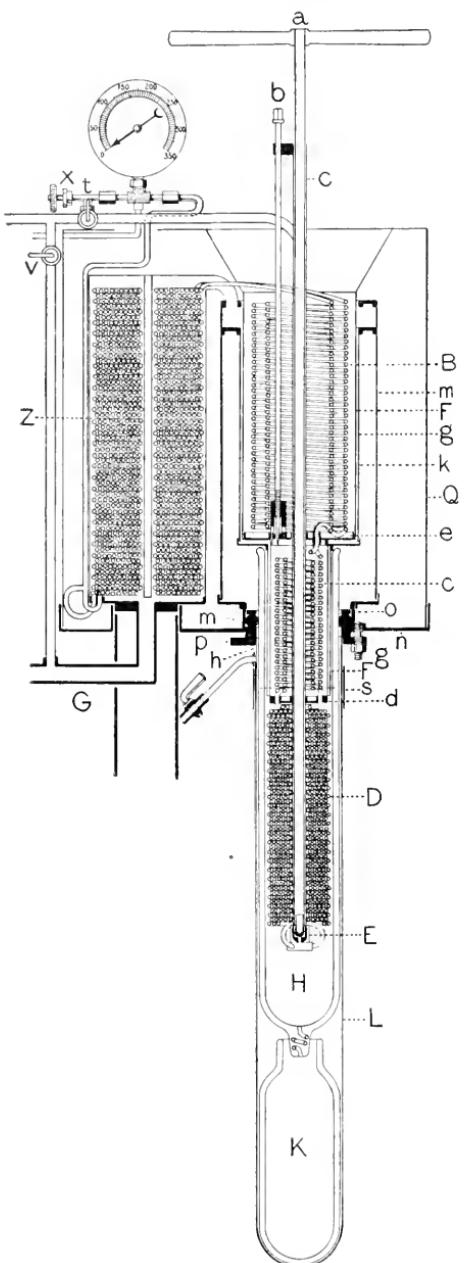

FIG. 6.—Hydrogen liquefier with second regenerator coil.

acid cooling chamber is replaced by the regenerator coil Z , and consequently the position of the escape pipe G is changed.

It might be expected, then, as the result of employing a second regenerator coil of sufficient length to produce a heat interchange so complete that the temperature would not differ by more than one or two degrees, that the gas would enter the coil in the liquid air chamber at a temperature not far from -170° C. instead of at -75° , as in the earlier forms of the apparatus. The liquid air would then serve to cool the gas only through 15° instead of through 110° , and, when the apparatus was once cooled down, it should consume only about one fifth of the liquid air required to maintain the older machine in action.

Though it is practically impossible to obtain accurate figures for the quantity of liquid air used in an experiment, I am satisfied that the results which I had predicted were fully realized in the apparatus which I next constructed.

The form of the liquefier is shown in fig. 6. It is practically identical with that last described, only the carbonic

The hydrogen enters the apparatus from the compressor at a distributing cross piece below the gauge, as in the last model, and passes first to the bottom of the regenerator coil Z . This consists of two pipes of 3.2 mm. external and 2 mm. internal diameter, wound coaxially to form a coil 300 mm. long and 100 mm. in diameter. The coil is covered with a layer of flannel and fits tightly into a brass case communicating above with the top of the annular space F and at the bottom with the escape pipe G . The upper end of the coil communicates with the coil in the liquid air chamber B .

The structure of the remaining parts of the apparatus is identical with that of the last model and needs no further description; though there is a slight difference in the arrangement of the pipes f and G and of the cocks t , V (and w), their uses are identical and a description of the method of manipulation of either apparatus will serve for both.

Olszewski* has described a liquefier somewhat similar to mine, though at the time at which his paper was published the apparatus had not been tested. He states that it is possible to liquefy hydrogen by cooling it to the temperature of liquid air boiling under normal pressure before allowing it to enter the regenerator coil (D , figs. 4, 6). It appears to me, however, that as the regenerator coil is of the same dimension as in my machine, Olszewski's apparatus will be found to be considerably less efficient.

Before describing my latest researches on the liquefaction of hydrogen it will be convenient to consider the method of compressing the hydrogen, and of manipulating the liquefier.

X. COMPRESSION OF THE HYDROGEN.

The Whitehead torpedo compressor, as employed in connection with the Hampson air liquefier, cannot be used for the compression of hydrogen without modification. In the usual form of this machine the packings of the pistons in both cylinders consist of cup-fibers carried on the ends of the pistons and moving with them. In fig. 7, A, the low pressure cylinder is shown in section. Air is drawn into the cylinder through the valve a and expelled through the valve b ; c is the piston, which carries the cup fiber d , and is actuated by means of the connecting rod e . The piston and cross head f are one solid piece of metal.

It will easily be seen that when gas is being compressed the contact between the edge of the cup-fiber and the walls of the cylinder is perfect, but that when gas is being drawn into the cylinder, the pressure in it falls below that of the atmosphere, and there is a tendency for air to enter it between the metal and the fiber. The extent to which this would take place would be considerably increased if the cross head became slightly worn and acquired a little side play.

* Acad. des Sci. de Cracovie, December, 1902.

In some of my earlier experiments I was considerably troubled by the presence of impurities in the hydrogen, and at last traced the trouble to this source. For some time I managed to get over my difficulties by replacing the low pressure cup-fiber each time I compressed hydrogen, but as this proved troublesome and unsatisfactory I resolved to modify the low pressure cylinder so as to completely eliminate all chance of further trouble.

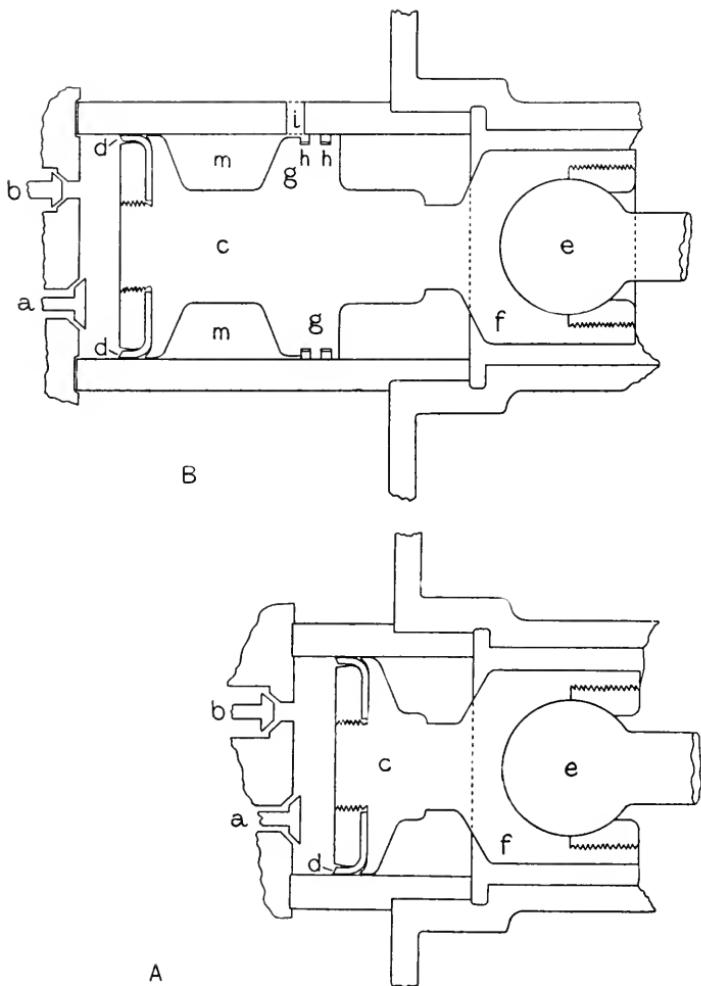

FIG. 7.—Hydrogen compressor.

The alterations were carried out by Brin's Oxygen Company. The new arrangement of the cylinder is shown in fig. 7, B. The length of the cylinder and of the studs which keep the cylinder cover in place was increased by 87 mm., the length of the stroke, and a second piston *gg*, with bronze rings of the usual pattern was introduced between the

original piston *c* and crosshead *f*. A hole *i* was bored in the top of the cylinder so that the space *mm* filled with water automatically from the tank in which the cylinder was immersed. If now the cup-fiber *dd* fitted the cylinder badly, only water could be drawn into the latter during the compression of the gas.

The whole arrangement for the compression and circulation of the hydrogen is shown in fig. 8. The hydrogen is conveyed from the gasometer, which is not shown in the figure, by a pipe *CC*, which communicates through a stopcock and connecting pipe with the low-pressure intake of the compressor *A*. The liquefying apparatus I have described was designed to work with about ten cubic meters of gas per hour. To deliver this quantity of gas the compressor must run at 360 revolutions per minute, and requires about seven horse-power to drive it.

Water mixed with about twenty percent of glycerol and one percent of caustic soda is drawn into the compressor from the reservoir *R*. The jet of the glass stopcock on *R* passes through a rubber cock in the neck of a small funnel which is connected below with the small cock on the intake pipe by means of a piece of rubber tube.

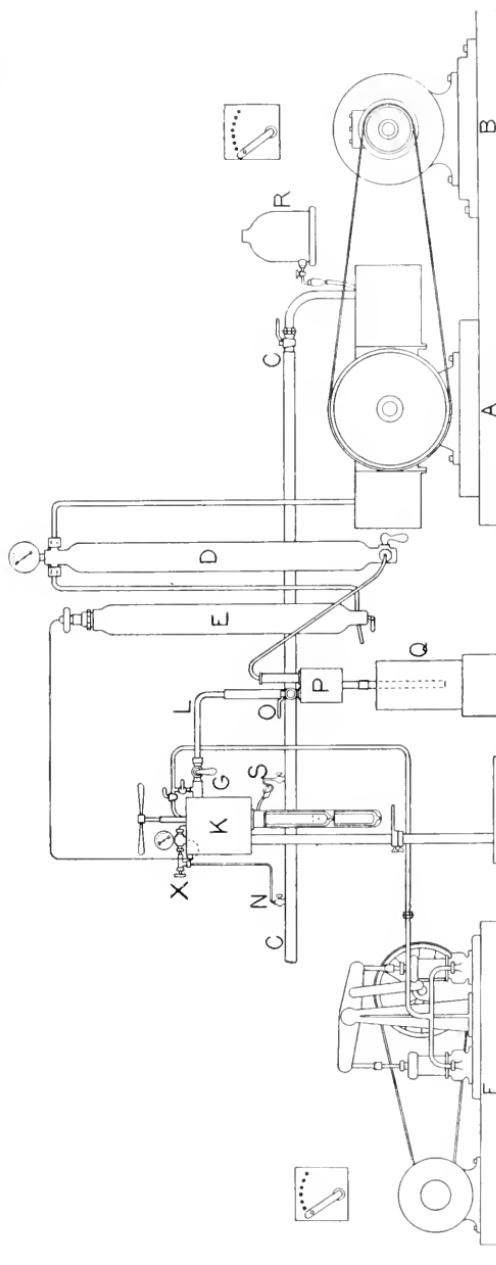

FIG. 8.—Arrangement of the liquefier, compressor, pump, etc.

The hydrogen is compressed in two stages, as described on page 23, and first enters the water separator *D* where the lubrication water is separated and discharged. The pipe from the cylinder *D* enters the collecting chamber *P*; the water runs into the tank *Q*, while the gas returns to the supply pipe *C*. The collecting chamber is shown in detail in fig. 9.

The compressed gas, which now contains only a trace of moisture, passes next through the cylinder *E* containing solid caustic potash, on its way to the liquefier *K*, which in the diagram is of the type described on pages 18-20. After undergoing compression, and partial liquefaction, the remaining gas returns by way of the pipe *L* to the distributing chamber *P*, and thence into the pipe *C*. Should the pressure rise suddenly through the blocking of the expansion valve, the cock *x* can be opened and some of the gas allowed to escape through a pipe which enters the supply pipe *C* through a small cock *N*. The connecting pipe *S*, which is of rubber, serves to prevent any waste through the escape of the hydrogen which passes out of the spiral opening at the bottom of the vacuum vessel *H* (figs. 5 or 6), when the liquid hydrogen runs into the receiving vessel (p. 20).

The operation of cooling down the liquefier has been described on page 19, and need not be dealt with again here. The next step in the operation was to remove the air from the compressor and purifying cylinders, and this was usually accomplished by starting the compressor two or three times, so as to take three or four cubic feet of gas into it on each occasion, and then allowing the compressed hydrogen to escape by opening a cock at the bottom of the potash purifier *D*. Later it was found to be much more effective to allow the hydrogen to pass completely through the apparatus and to escape at the expansion valve. In this case, the "washing out" of the apparatus had to be completed before the cooling down was commenced.

After washing out the apparatus the motor was again started and the pressure was allowed to rise.

Meanwhile the cap and the tap *V* (see page 20, fig. 5) had been removed from the bottom of the vacuum vessel *H*, and the liquid air was allowed to drain out of it. The collecting vessel *K* was now placed inside the tube *L* (figs. 4 or 6), and the latter was placed in position as shown in the figure. The connection between the tube *L* and the brass tube *h*, which formed part of the gland *p*, was made by means of a rubber sleeve *s*, secured to both by means of a tube of copper wire. When the sleeve was in position gas could only escape from the space within the tube *L* through the cock *r*, so that when the latter was closed the liquid which formed in *H* could not flow into *K*. When, however, the cock *r* was opened, liquid and gas could flow from *H* into *K*, the gas passing through the cock *r* and the tube *S*.

(figs. 4, 6, 8) to the main hydrogen supply pipe. The cock *r* was not opened till the liquefaction of the hydrogen had commenced.

The tube *L* was usually surrounded either by a large vacuum vessel or by three concentric glass shades, spaced apart with asbestos mixed with a little pentoxide of phosphorus to absorb moisture from the surrounding air. This arrangement prevented the deposition of moisture on the walls of the tube *L* and enabled one to see what was taking place inside.

When the pressure in the apparatus had risen to 150 atmospheres the expansion valve was slowly opened and for a few moments the hydrogen was allowed to escape from the circulation system, either by bubbling through the water in the tank *Q*, fig. 8, or by opening the cock *O'* (fig. 9). When sufficient hydrogen had been allowed to escape, and the apparatus was considered to be free from air, the cock *O'* (fig. 9), was closed, the cock *O* was opened and the hydrogen was allowed to circulate through the system.

Shortly after commencing the expansion a small quantity of solid impurity always separated in the bottom of the vacuum-vessel *H* (figs. 4, 6). It is noteworthy that the solid impurity never blocked the coil, though it is probable that the latter was cooled to below the critical point of hydrogen, but seemed to encrust the valve at the point at which the expansion took place. Hannay* pointed out some years ago that gases under high pressure, particularly in the neighborhood of their critical points, were able to hold solids in solution; considering the complete continuity of the liquid and gaseous states of matter this is hardly remarkable. To this phenomenon, which is allied to that of retrograde condensation in the case of mixed gases, is due the fact that the coils are never blocked by the presence of impurities, which at the temperatures to which the gas is cooled should behave as non-volatile solids, but which are dissolved by the compressed gas in the coil.

When the liquefier is working well it should require about half an hour from the time of commencing operations to fill a receiving vessel (*K*, figs. 4, 6) holding about half a liter. When once liquid hydrogen is formed, and the cock *r* is opened, the liquid falls in large drops from the nozzle of the vessel *H*. The liquid is usually slightly milky at first, but the solid impurity soon settles to the bottom of the receiving vessel, leaving the liquid clear.

When the receiving vessel is full the tube *L* can be lowered, and the receiving vessel drawn out of it by means of a wire attached to it. The receiving vessel is at once plugged with wool and placed inside a second vessel containing liquid air.

In machines which required solid carbonic acid about four kilos of that substance was required at each experiment, together with about

* Proceedings of the Royal Society, 1879, Vol. 30, 484.

eight liters of liquid air. With these quantities the apparatus could be run for about thirty minutes. With the apparatus having the second regenerator coil, which did not require carbonic acid, five liters of liquid air fully sufficed to cool the apparatus in the first place and to cool the hydrogen during a run of more than twice the duration of the former experiments.

The collecting chamber referred to on page 20 is a cylindrical brass box about 80 mm. in diameter and 100 mm. high. The tube γ is con-

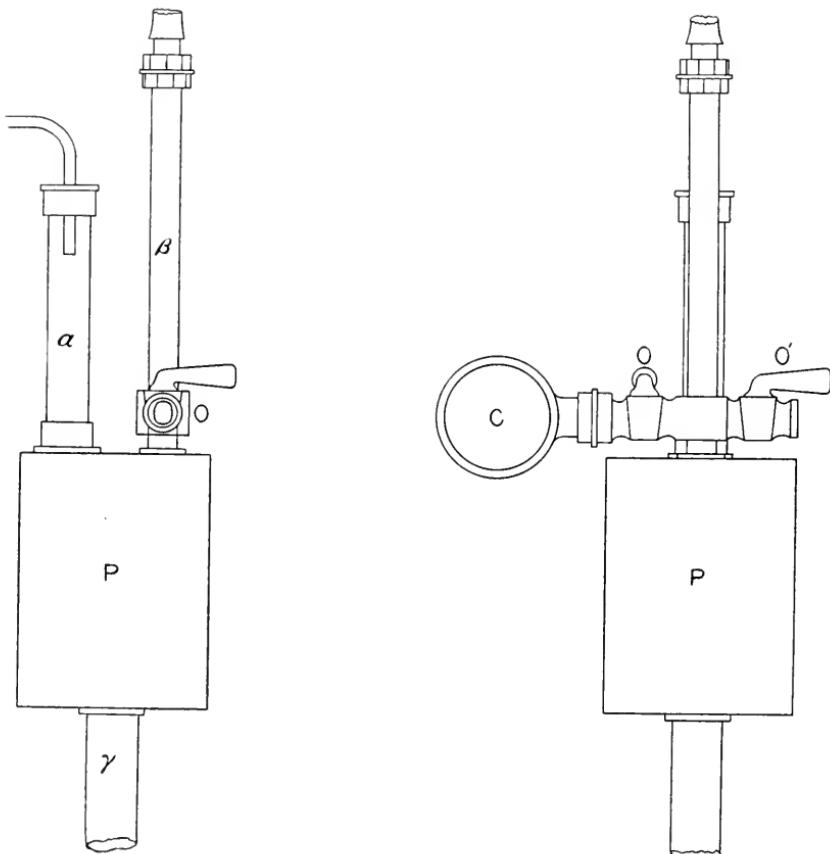

FIG. 9.—Collecting chamber.

nected by means of a piece of wide rubber tube with a brass tube of similar diameter which dips about 50 cm. below the surface of the water in a tank Q , fig. 8. The tube α is of glass, joined by means of a socket with the cylinder P , and by a cap with the pipe through which water is discharged from the water separator D , fig. 8. By means of this arrangement the gas discharged together with the water is saved. The pipe β is connected by means of a crosspiece with the body of the apparatus and with the two cocks O and O' . The cock O

communicates directly with the pipe *C* leading from the gasometer to the compressor, and through it the hydrogen which returns from the liquefier through the tube *G*, figs. 3, 4, 6, *L* fig. 8 and *a* fig. 9, can be returned to the circulation system. The hydrogen which escapes from the liquefier when the expansion is first commenced, is allowed to escape through the cock *O'*, which is closed before the cock *O* is opened. The pipe *y* serves not only to discharge the water delivered through *a*, but also as a safety valve.

XII. THE PREPARATION OF THE HYDROGEN.

In my earlier experiments I prepared the hydrogen by the action of dilute (25 percent) sulphuric acid on commercial zinc, contained in a beer barrel, which had received several coats of enamel paint. Since, however, it appeared that the gas suffered both loss and contamination by diffusion through the walls of the barrel, I replaced it by a lead vessel. The apparatus for generating the hydrogen is shown in fig. 10.

The vessel *A*, which was 500 mm. high and 300 mm. in diameter, was made of sheet lead, "burnt" at the junctions in the oxy-hydrogen blow-pipe. At the commencement of each operation it usually contained about fifteen kilograms of pure granulated zinc. Dilute sulphuric acid containing little copper sulphate was run into *A* in a steady stream from the reservoir *B*, and as the zinc sulphate solution accumulated it was run off through the stop-cock *E*. The hydrogen could either be allowed to escape through the pipe *C*, which was plunged into a deep vessel filled with water, and acted as a safety valve, or to pass along the pipe *D* into the purifying towers *F*, *F'*.

The towers *F*, *F'*, *F''* were filled with broken pumice, which was kept wet by means of solutions of the reagents contained in the reservoirs *G*, *G'*. The first of these, which supplied the first two towers, contained an acid solution of chromic acid, the second contained silver nitrate solution, which served to remove arseniureted hydrogen from the gas. The excess of the reagents flowed through inverted siphons, which acted as gas traps, at the bottom of the towers, and was collected in the vessels *H*, *H'*.

The gas finally passed through a solution of caustic potash contained in the vessel *K* and entered the pipe leading to the gasometer through the cock *L*.

If the gasometer already contained some hydrogen this gas could be used to wash out the generating apparatus before introducing the fresh quantity of gas. This could easily be done by first lowering the reservoir *J*, so as to empty the vessel *K*, and thus raising the tube *C* till the gas bubbled through the water in which it was immersed, and escaped.

XIII. THE GASOMETER.

The gasometer in use at University College, London, is of the simple type shown in fig. 11, A. It consists of two cylindrical tanks, one enclosing the other. The outer tank is 2,000 cm. high and 1,500 cm. in diameter, the inner one is 1,800 cm. high and 1,450 cm. in

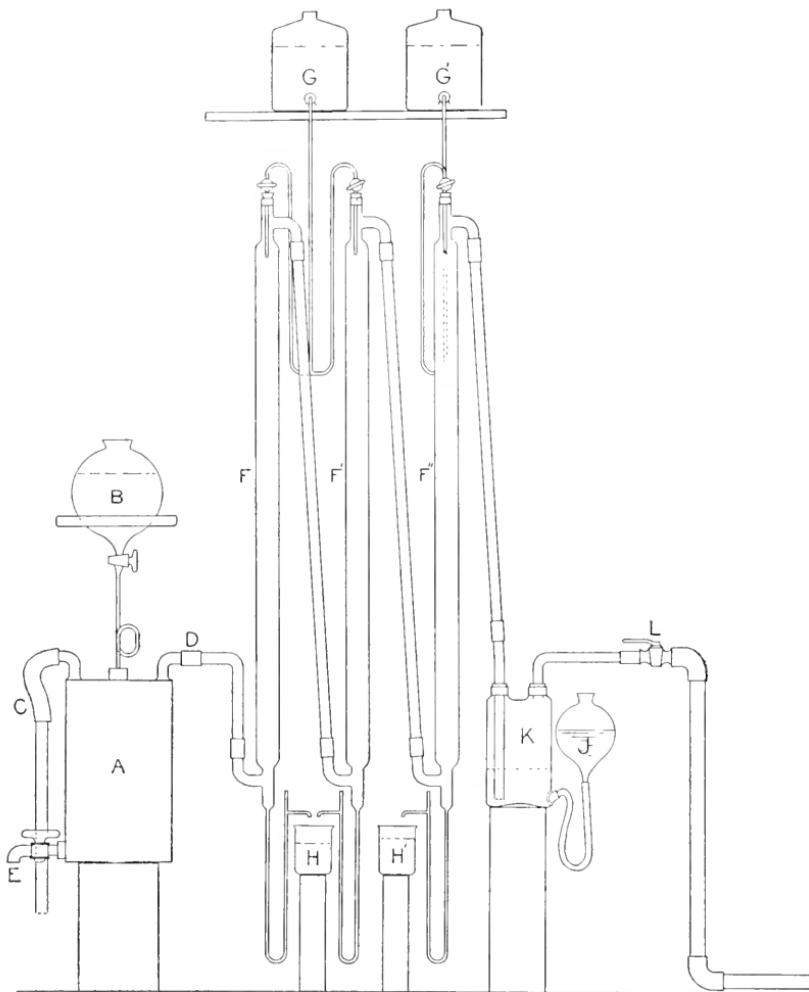

FIG. 10.—Apparatus for generating the hydrogen.

diameter. The outer tank is filled with water to just above the level of the top of the inner tank. The supply pipe passes through the center of the gasometer, and opens inside a small dome in the top of the inner tank. This enables practically the whole of the gas to be easily expelled from the gasometer.

When it was first placed in position the water in the gasometer was saturated with hydrogen by passing a stream of that gas through it from a small generator. The gas passed to the bottom of the tank by

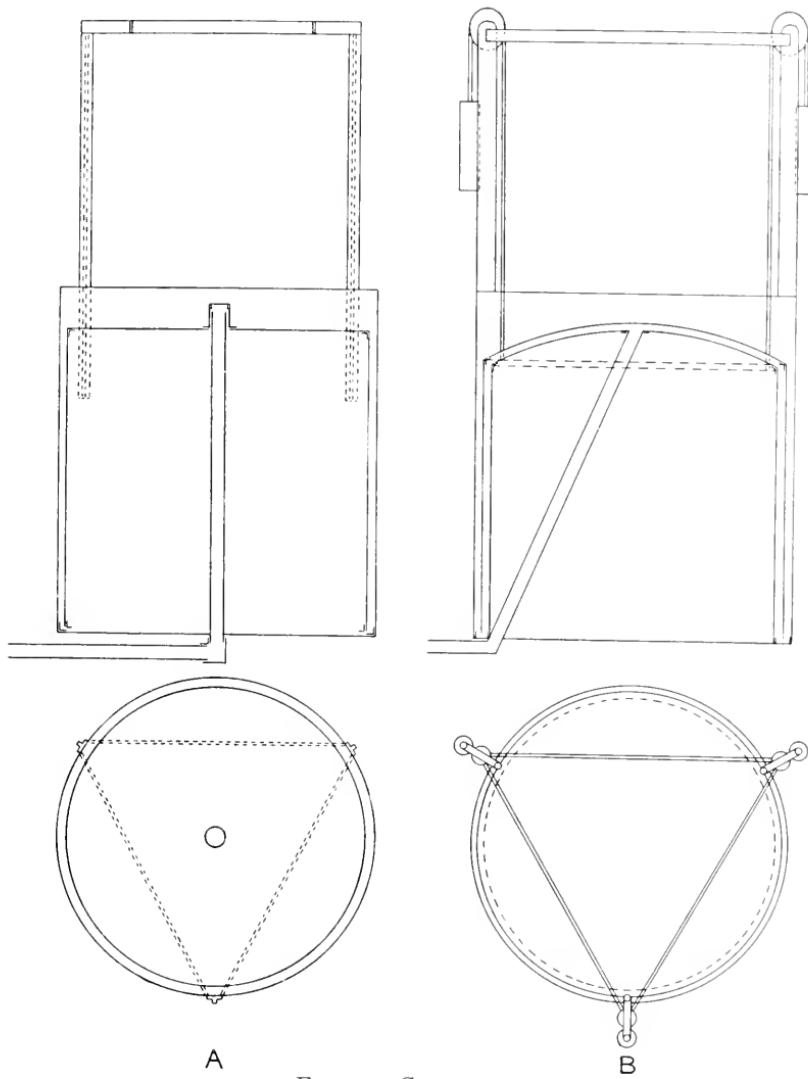

FIG. 11.—Gasometers.

means of a piece of composition gas pipe. The operation of saturating the water occupied nearly a week; it was not, however, necessary to repeat it as the gasometer always contained hydrogen.

The pressure inside the gasometer was equivalent to about 500 mm. of water.

Though for financial reasons I was obliged to content myself with

a gasometer of the type I have described, there is a considerable advantage in one of the kind shown in fig. 11, B. Such a gasometer is in use in connection with the liquefaction plant which I designed for Professor Auschütz of Bonn. Gasometers of this type are used for the storage of acetylene.

XIV. CONCLUSION OF PART I.

I have so far succeeded in designing an apparatus by means of which I can at a comparatively small cost produce quantities of liquid hydrogen sufficient for experimental purposes. I have usually obtained half a liter as a maximum quantity, as it has always been sufficient for the experiments I have had in hand.

I am at present engaged in designing an apparatus in which the liquid hydrogen will be produced inside a metal chamber, and will be drawn off through a cock. The elimination of the glass vacuum vessel presents obvious advantages. At the same time I am investigating the conditions most favorable to effective heat interchange in the regenerator coil *D*, figs. 4, 6, of the apparatus. The dimensions of the coils (p. 16) in the machines I have already experimented with has always been one quarter of the size of the coil of the Hampson air liquefier, the temperature gradient being in one case 50° and in the other 200° . The results of my experiments appear to indicate that these dimensions are too small, for the reason that the heat interchange is a function not only of the conductivity of the metal of which the coils are constructed, but also of certain properties of the gas. Further, it appears probable that the spacing of the coils will have a considerable influence on the efficiency of the apparatus, and that for hydrogen, which has a low viscosity, the coils should be closer together than in a machine which is designed to liquefy air.

In conclusion I wish to express my indebtedness to the Smithsonian Institution for the assistance it has given me in carrying out these investigations.

SMITHSONIAN MISCELLANEOUS COLLECTIONS

PART OF VOLUME XLVI

A CATALOGUE OF
NORTH AMERICAN DIPTERA
(OR TWO-WINGED FLIES)

A CATALOGUE OF NORTH AMERICAN DIPTERA

BY J. M. ALDRICH.

INTRODUCTION.

The present work is based upon Osten Sacken's Catalogue of North America Diptera, second edition, published in 1878.* All the references of that work are embodied in this, with only such changes as later studies seem to require.

Still, the great amount of work which has been done on North American Diptera within the quarter of a century has largely changed the face of the subject. Hence the reader will probably observe, especially at first, more of contrast than resemblance. The number of species has doubled; the number of references to previously known species has almost doubled; several families have been monographed or revised, with more or less change of nomenclature; along with this has gone the publication of a multitude of smaller papers, touching every family but one, and the larger part of the genera. Under these conditions it is inevitable that great changes should appear in the new catalogue. It is the more necessary that I should acknowledge my obligation, which is far greater than appears on the surface.

Faunal limits.—These, as in the former catalogue, include all of North America, in the widest sense, taking in Panama on the South and Greenland and the Aleutian Islands on the North. The West Indies are included, even down to Trinidad, adjoining Venezuela. There is no place to draw a line between the islands. The Bermudas and the Hawaiian Islands are not included.

Scope.—To give the most information consistent with the limits of space has been the object. All references to a species, if in any way descriptive or useful, have been inserted if found. The only known exceptions are in those species like the Hessian fly and house-fly, where the references are so numerous that a selection of the more important articles is necessary. Another exception is uniformly made of articles in non-scientific journals; these are only mentioned when of importance in tracing the history of a species.

* Smithsonian Miscellaneous Collections, Vol. xvi.

Professor J. H. Comstock extended courtesies when I was visiting Cornell. In his department I examined a considerable collection of Diptera determined by Osten Sacken and Williston, also some interesting literature. In the Cornell University library I found "Silliman's Journal."

Mr. Samuel Henshaw assisted me very kindly when I examined some families in the Loew-Osten Sacken collection at Harvard University.

Dr. Garry de N. Hough gave me some unpublished notes, and a large number of Diptera.

Mr. O. A. Johannsen, of Cornell University, revised the classification of the Chironomidae for me, greatly improving my work on that family.

Mr. Hugo Kahl gave me unpublished notes of his own; he also gave me minute directions about some points to look up in the Loew-Osten Sacken collection, the outcome of which gave me a very high opinion of Mr. Kahl's acuteness in systematic work, and revealed some peculiar errors of Loew in describing two or three species.

To W. D. Hunter, C. W. Johnson, C. T. Brues, and Professors V. L. Kellogg and C. V. Piper, I am indebted for references to literature.

Mr. A. L. Melander gave me great assistance in the Empididae. I have followed his advice quite uniformly in regard to nomenclature and synonymy in that family.

I have availed myself of Dr. Coloman Kertész's great work, "Catalogus Dipterorum," of which two volumes have reached me, only to the extent of adopting the generic distribution of the Cecidomyidae, and of picking up one species—*Culex penaflicli* Will.—which I had not found before. My work was almost completed when the first volume of Kertész came out.

To all the gentlemen named, I extend my sincere thanks.

The catalogue closes January 1, 1904.

J. M. ALDRICH.

UNIVERSITY OF IDAHO,
January 27, 1904.

SYSTEM OF CLASSIFICATION ADOPTED.

Suborder PROBOSCIDEA.

Section ORTHORHAPHA.

Division *Nemocera*.

Superfamily 1.—*Nemocera Vera* :—*Tipulidæ, Dixidæ, Psychodidæ, Chironomidæ, Culicidæ, Mycetophilidæ, Cecidomyiidæ*.

Superfamily 2.—*Nemocera Anomala* :—*Bibionidæ, Simuliidæ, Blepharoceridæ, Rhyphidæ, Orphnophilidæ*.

Division *Brachycera*.

Superfamily 3.—*Eremochæta* :—*Stratiomyidæ, Tabanidæ, Acanthomeridæ, Leptidæ (inclusive of Xylophagidæ and Coenomyidæ)*.

Superfamily 4.—*Tromoptera* :—*Nemestrinidæ, Cyrtidæ, Bombyliidæ, Therevide, Scenopinidæ*.

Superfamily 5.—*Mydaidæ* :—*Mydaidæ*.

Superfamily 6.—*Energopoda* :—*Apioceridæ, Asilidæ, Dolichopodidæ, Empididæ, Lonchopteridæ, Phoridae*.

Section CYCLORHAPHA.

Division *Athericera*.—*Platypezidæ, Pipunculidæ, Syrphidæ, Conopidae*.

Division *Calyptratæ*.—*Œstridæ, Tachinidæ, Dexiidæ, Sarcophagidæ, Muscidæ, Anthomyiidæ*.

Division *Acalyptratæ*.—*Scatophagidæ, Heteroneuridæ, Helomyzidæ, Borrividæ, Phycodromidæ, Sciomyzidæ, Sapromyzidæ, Lonchæidæ, Ortalidæ, Rhopalomeridæ, Trypetidæ, Micropezidæ, Sepsidæ, Psilidæ, Diopsidæ, Ephydriidæ, Oscinidæ, Drosophilidæ, Geomyzidæ, Agromyzidæ*.

Suborder EPROBOSCIDEA.

Hippoboscidæ, Nycteribiidæ.

BIBLIOGRAPHY.

Adams, C. F.

Dipterological Contributions. Kans. Univ. Sci. Bull., II, 21-47; June, 1903.
Contains 37 new species from North America, and 7 from S. Africa; also some tables of genera.

Six new species of Diptera from Kansas, appended to Snow's List. Kans. Univ. Sci. Bull., II, 221-223; Nov., 1903.

Aldrich, J. M.

A New Genus and Species of Tabanidae. Psyche, VI, 236, figs.; March, 1892.
Goniops hippoboscoides, n. gen. and sp. (syn. of *chrysocoma* O. S.).

New Species of Phora. Canadian Entomologist, XXIV, 142-146, figs.; June, 1892.

Phora cimbicis, *luggeri*, *minuta*, and *setacea*; table of species.

Revision of the Genera Dolichopus and Hygrocoleuthus. Kansas Univ. Quart., II, 1-26, 1 pl.; July, 1893.

Twenty-two new species; table of species, etc.

New Genera and Species of Psilopinae. Kansas Univ. Quart., II, 47-50; July, 1893.

Three genera and four species; *Leptorhethum* is the only genus of Psilopinae which I now retain as given in this article.

The Dolichopodid Genus Liancalus Loew. Psyche, VI, 569-571; Dec., 1893.
L. hydrophilus and *similis*; table of species.

Courtship Among the Flies. American Naturalist, XXVIII, 35-37; Jan., 1894.
Habits of some species of *Dolichopus*.

New Genera and Species of Dolichopodidae. Kansas Univ. Quart., II, 151-157; Jan., 1894.

Two new genera and five new species; notes on other described western species.

The Tipulid Genera Bittacomorpha and Pedicia. Psyche, VII, 200-202, fig.; Feb., 1895.

Bittacomorpha occidentalis, n. sp.

The Dipterous Genera Tachytrechus and Maccellocerus. Trans. Amer. Ent. Soc., XXIII, 81-84; March, 1896.

Tachytrechus floridensis; *Maccellocerus olympiae* and *auratus*.

On the Diptera of St. Vincent: Dolichopodidae and Phoridae. Trans. Ent. Soc. London, 1896, pt. 3, pp. 309-345 and 435-439.

Many new species, tables in several genera, and notes on described species.

A Collection of Diptera from Indiana Caves. 21st Annual Report of the Department of Geology and Natural Resources of Indiana, 186-190; published May 6, 1897.

Odontopoda, n. gen.; *Mycetophilus umbraticus*, *Odontopoda sayi*, *Blepharoptera latens* and *specus*, *Limosina tenebrarum*; notes on other species.

Goniops and other Synonyms. Entom. News, XI, 531; Sept., 1900.

No new species.

Biologia Centrali-Americanica: Diptera, I., Suppl., 333-366, 1 pl.; Dec., 1901.

Dolichopodidae: 47 new species; *Sarcionus* and *Phylarchus*, n. gen.

Dolichopodidae of Grenada, W. I. Kans. Univ. Sci. Bull., I, 75-94, 1 pl., March, 1902.

Fourteen new species; *Xanthina*, new genus.

Aldrich, J. M., and Turley, L. A.

A Balloon-making Fly. American Naturalist, XXXIII, 809-812, figs.; 1899.

The species here discussed was afterwards described as *Empis aerobaticus* by Mr. Melander.

Austen, E. E.

Descriptions of New Species of Dipterous Insects of the Family Syrphidae in the Collection of the British Museum, with Notes on Species Described by the late Francis Walker. Part I. Bacchini and Brachyopini. Proc. Zool. Society of London, Jan. 17, 1893, pp. 132-164, 2 col. pl.

Ocyptamus iris and *Baccha sagittifera*, from Jamaica; many important notes on Walker's types and other species.

On the Specimens of the Genus *Cutiterebra* and Its Allies in the Collection of the British Museum, with descriptions of a new Genus and Three new Species. Annals and Magazine of Natural History, Ser. 6, Vol. xv, 377-396, 1 pl.; May, 1895.

Cutiterebra funcbris (Trinidad), *approximata* Walk. (Vancouver); *Bogeria princeps*, n. gen. and sp., Mexico; other important notes.

Further Notes on *Cutiterebra*: On the Identity of Certain Species Described by the late Bracy Clark. Annals and Magazine of Natural History. Ser. 6, Vol. xvi, 147-155; August, 1895.

C. atrox, detrudator and *fontinella* of Clark.

Notes on Hippoboscidae in the Collection of the British Museum. Annals and Magazine of Natural History. Ser. vii, Vol. XII, 255-266; Aug., 1903.

Important notes on species of Wulp and Walker; no new species.

Babb, Geo. F.

Notes on *Rhagoletis snavis*, with desc. of larva and puparium. Ent. News, XIII, 242, 1 pl.; Oct., 1902.

Baker, C. F.

Biological Notes on some Colorado Diptera. Ent. News, VI, 173, 174; June, 1895.

Records rearing of twelve species.

Banks, Nathan.

Some Psychodidae from Long Island. Canadian Entomologist, XXVI, 329-333; Dec., 1894.

Psychoda nigra, minuta, superba, bicolor; table of species.

Notes on *Psychoda*. Canadian Entomologist, XXVII, 324; November, 1895. *P. albatarsis*, Ithaca, N. Y.

Syrphidae of Long Island, N. Y. Journal of the N. Y. Ent. Society, V, 40, 41; 1897.

A list of species collected at Sea Cliff, L. I.

The Eastern Species of *Psychoda*. Canadian Entomologist, XXXIII, 273-275; Oct., 1901.

P. signata, opposia, nitida.

Concerning *Gastrophilus cpilepsalis* French. Canadian Entomologist, XXXV, 333, 1903.

Becker, Theodor.

Die Phoridae. Abhandlungen der K. K. Zool.-Botan. Gesellschaft in Wien. I, Heft. 1, pp. 1-100, 5 plates; 1901.

Note.—These recent monographs of European Diptera are admirably executed, and are especially useful to the American student for genera. A considerable number of the species are common to Europe and North America.

Bellardi, Luigi.

Saggio di Ditterologia Messicana. Two parts and supplement, with five plates. Mem. della Reale Accad. delle Scienze di Torino, Ser. 2, Vol. xix, 201-277, 2 plates, 1859; xxi, 103-199, and Appendix, 200-225, with 3 plates, 1861-62. Also published separately with a different pagination.

Apelleia, n. g.; many new species. Osten Sacken gives the pages as they occur in the separate edition, which I follow.

Bergroth, Evald.

Note on some South African Tipulidae. Entom. Tidskrift, ix, 1888.

Contains a note on *Holorusia rubiginosa*. I am indebted to Professor V. L. Kellogg for this reference.

Ueber einige Nordamerikanische Tipuliden. Wiener Entom. Zeitung, vii, 193-201; June, 1888.

Eight new species, with notes on several others.

The same, Part II. Pp. 239, 240; Sept., 1888.

Pachyrhina excelsior, n. sp., and several notes.

Zwei neue Dipteren. Wiener Entomol. Zeitung, viii, 295-298; Nov., 1889.

One is from New Zealand, the other is *Dialysis disparilis*, from British Columbia; there is an additional note on the latter, Vol. xi, 162.

Buetenmüller, Wm.

Essay on the Destruction of the Mosquito and the House-fly. 180 pp., 2 plates; 1890.

Cecidomyia clavula, n. sp. Bull. American Museum of Natural History, iv, 1892, 269, pl. xv, f. 5.

Gall only.

Bigot, Jacques.

Diptera of Cuba. In "Historia fisica, política y natural de la Isla de Cuba," by Ramon de la Sagra, Paris, 1857, Vol. vii, with one plate. "Published in French and in Spanish; the French edition is quoted in the catalogue, the Spanish has a different pagination"—O. S. Not seen.

Twenty-five new species.

Dipterorum aliquot nova genera. Revue et Magazin de Zoologie, 1859, 305-315, pl. xi.

Hystrisiphona nigra, *Cryptineura microglyphica*.

Leptidi. Bulletin de la Société Zoologique de France, XII, 1-22, 1887.

21 N. A. species.

Muscidii. Bulletin de la Société Zoologique de France, XII, 581-617, 1887.

16 N. A. species.

Tabanidi. Mémoires de la Société Zoologique de France, V, 602-690, 1892.

26 N. A. species.

Notes on North American Diptera, with new genera and species, published in Bulletin de la Société entomologique de France, as follows:

Year.	Pages.	Subject.
1875	clxxiv (196)	Thevenimyia californica.
1877	xxvi (38)	Carlottæmyia mœrens.
1877	Ixxiii (101)	Macroceromys.
1879	1, li (64)	Merapioidus villosus.
1879	86	Parasynnictus.
1879	164, 165	Notes on Arthropeas and Glutops.
1879	231, 232	Corrections to article in Annales, 1879, 183-234.
1880	5	Megalemyia argyropasta, Acanthomera rubriventris.
1880	62, 63	Phylloonydas phyllocerus, Enoplempis mira, Megacittarus argenteus.
1882	4	Syrphidae.
1882	19-21	Corrections; Lycastrirrhyncha, etc.
1882	78, 79	Eurhinomallota metallica.
1882	112	Myelaphus melas, Enoplempis cinerea.
1883	35	Proboscimyia siphonina.
1884	xxix (34, 35)	Mikimyia furcifera.
1884	42	Cholomyia inæquipes.
1884	95	Ancylogaster armatus.
1884	xcvii	Euceratomyia Will., note.
1884	cxxxvi	Merapioidus; reply to Williston, Wien. Ent. Zeit., 1884, 282.
1885	clxyi (sep. 1)	Stictomyia longicornis, Dimorphomyia calliphoroides.
1885	sep. 1-7	Rhamphinina dubia, Rhynchodexia tenuipes, Siphoniomyia melas.
1886	clxvii, clxviii	Notes on Osten Sacken's Acanthomeridae in Biologia.
1886	sep. 1-4	Rhabdopselaphus mus.
1887	lx	On Eclinus, Epibates and Thevenimyia.
1887	cxxi-cxxiii	Notes on Williston's Synopsis N. A. Syrphidae.
1887	clxxii-clxxiv (180-182)	Diagnoses of Muscidæ, several species.
1888	xxiv et seq.	Psilopodinus, Spatichira, etc.
1888	cvi, cvii	Corrections.
1888	clxxxiii	Notes on Archilestes; Pseudarchilestes.
1892	xxxvi-xxxviii	Notes on Williston's synonymy in Biologia.

Note.—Bigot's main work, as will be seen from the tables above, is in the form of a long series of articles in the Annales Soc. ent. France (quoted herein merely as "Annales"), interspersed chronologically with fragments in the Bulletin of the same society. Owing to Bigot's peculiar, complicated and inconsistent system of numbering his contributions, it has been almost impossible for

me to find them all, but I believe I have succeeded. I have seen no correct collation. Sometimes his Roman numerals stop and remain the same for several papers, then again the numbering in "parts" becomes stationary while the other goes on, and in two cases two papers have both the same (XXXVII, part 29, and XLII, part 34).

In the Bulletin the confusion is worse confounded. This publication appears to have been for some time regularly published in two forms, one numbered in Arabic, and the other differently paged in Roman. I am unable to decipher all the peculiarities of this, but am obliged to refer partly to one, partly to the other, and occasionally to separates, as my copies run, or as I find indications in the references of others. I possess all the papers of the Annales series, and all but two small ones of the Bulletin series; but the accumulation was the work of ten years.

The work of Bigot should not be underestimated. He had a fine collection, and his types are now the property of Mr. G. H. Verrall. It is only a question of time until they will be elucidated; in fact, this has already been done for the Calypratae (excl. of Anthomyidae) by Brauer, and for the Pupipara by Speiser. As the descriptions stand, it is often impossible to determine the species from them alone. It is not unlikely that some of them have been assigned to synonymy too hastily.

Biologia Centrali-Americana.

For convenience of reference, I give a complete collation of the parts of this great work.

Volume I. Cecidomyiidae to Empidae. Pp. 1-216, 3 col. pl., by C. R. Osten Sacken.

Dates—pp. 1-24, July, 1886; 25-48, Aug., 1886; 49-72, Oct., 1886; 73-104 Nov., 1886; 105-128, Dec., 1886; 129-160, Jan., 1887; 161-176, Feb., 1887; 177-208, Mar., 1887; 209-216, April, 1887.

Volume I, Supplement. Pp. 217-378, 3 col. pl.

Mycetophilidae to Asilidae, pp. 217-332, by S. W. Williston.

Dates—pp. 217-248, Dec., 1900; 249-264, April, 1901; 265-272, May, 1901; 273-296, June, 1901; 297-328, Sept., 1901; 329-332, Dec., 1901.

Dolichopodidae, pp. 333 to 366, Dec., 1901, by J. M. Aldrich.

Empididae, pp. 366-376, Dec., 1901, by W. M. Wheeler and A. L. Melander.

List of Species Recorded since 1887, not enumerated in Suppl., 377, 378; Dec., 1901.

Volume II. Oestridae to Hippoboscidae. Pp. 1-432, 12 col. pl., by F. M. Van der Wulp.

Dates—pp. 1-40, April, 1888; 41-56, Jan., 1890; 57-88, Feb., 1890; 89-112, Mar., 1890; 113-144, May, 1890; 145-176, June, 1890; 177-200, Aug., 1890; 201-208, Nov., 1890; 209-224, April, 1891; 225-248, May, 1891; 249-264, July, 1891; 265-272, Dec., 1895; 273-280, Jan., 1896; 281-288, March, 1896; 289-304, May, 1896; 305-312, June, 1896; 313-320, Oct., 1896; 321-344, Dec., 1896; 345-360, Sept., 1897; 361-368, Nov., 1897; 369-376, Dec., 1897; 377-384, Oct., 1898; 385-392, Feb., 1899; 393-408, Sept., 1899; 409-416, Dec., 1899; 417-428, Feb., 1900; 429-432, Apr., 1903.

Volume II, Supplement. Pp. 433-486, 1 col. pl. Oestridae and Tachinidae, by F. M. Van der Wulp.

Dates—pp. 433-436, April, 1903; 437-486, May, 1903.

List of Species described since 1888, not enumerated in Vol. II., pp. 486-489, May, 1903.

Volume III. Syrphidae, Conopidae, Pipunculidae and Platypezidae. Pp. 1-89, 2 col. pl. By S. W. Williston.

Dates—pp. 1-56, Dec., 1891; 57-72, Feb., 1892; 73-89, May, 1892.

List of Species described since completion of volume, pp. 89-91, Aug., 1903.

Index to vols. I-III, pp. 93-127, Aug., 1903.

The last issue for each volume includes title-page, introduction, and explanation of plates, which do not interfere with the regular pagination of the text.

Bilimek, Dominik.

Fauna der Grotte Cacahuamilpa in Mexico. Verhandl. Zool.-Bot. Ges., 1867, p. 901.

Pholcomyia leucozona, n. g. and sp.

Bosc D'Antic, Louis A. G.

Ceroplatus carbonarius, from Carolina, described in Dictionnaire d'Histoire Naturelle, Paris, 1802-04, pub. by Déterville et Roret; the same is in Nouveau Dict. D'Hist. Nat., Paris, 1816-19.

Brauer, Friedrich,

Monographie der Oestriden. Wien, 1863, 292 pp., with 10 plates.

This classic monograph contains descriptions of all the Oestridae at that time known from North America. Only one is new, *Cuterebra scutellaris*. Beschreibung neuer und ungenügend bekannter Phryganiden und Oestriden. Verhandlungen der Zool.-Bot. Ges. zu Wien, 1875, 75. *Hypodermia bonassi*, on the American bison.

Die Zweiflügler des Kaiserlichen Museums zu Wien. In the Denkschriften der Mathematisch-Naturwissenschaftlichen Classe der Kaiserlichen Akademie der Wissenschaften.

I. In Band XLII, 1880.

1. Die Kaiserliche, Winthem'sche, Wiedmann'sche und Egger'sche Sammlung. Pp. 105-107.
2. Bemerkungen zur Systematik der Dipteren. Pp. 108-118.
3. Die Europäischen Arten der Gattung *Tabanus* L. s. str., etc. Pp. 119-210, six plates.

II. In Band XLIV, 1882.

1. Versuch einer Characteristik der Gattung der Notacanthen (Ltr.), mit Rücksicht auf die . . . von J. R. Schiner aufgestellten neuen Gattungen. Pp. 59-89.
2. Vergleichende Untersuchungen der Flügelgeäders der Dipteren-Familien nach Adolph's Theorie. Pp. 90-97, two plates.
3. Characteristik der mit *Scenopinus* verwandten Dipteren-Familien und Gattungen. Pp. 98-110.

III. In Band XLVII, 1883.

1. Systematische Studien auf Grundlage der Dipteren-Larven nebst einer Zusammenstellung von Beispielen aus der Literatur über dieselben und Beschreibung neuer Formen. Pp. 1-100, five plates.

The number on *Notacantha* contains *Cynipimorpha bilimcki* n. g. et sp. and *Myrosargus fasciatus* n. sp., from Mexico. The last number, on the dipterous larvae, is a great work. The numbers on classification represent extensive research, and the system of Brauer seems to be widely accepted in Europe at present; but I agree with Osten Sacken that classification is not the field in which Brauer has done his best work.

See continuation of the series by Brauer and von Bergenstam

Systematische-zoologische Studien. Sitzungsberichte d. Kaiserl. Akad. d. Wissenschaften, xcI, 237-414, 1 plate; 1885.

Asilus mydas and *Calobata ichneumonea*, n. sp. from Mexico.

Beiträge zur Kenntniss der Muscaria schizometopa. Sitzungsbericht. d. Kaiserl. Akad. der Wiss., Math.-Naturwiss. Classe, in three parts:

I. Band cxi, 329-382; July, 1897.

II. Band cxii, 493-546; June, 1898.

III. Band cxiii, 495-529; June, 1899.

These articles give a report on the types of Bigot's species in the families of the Calyptratae, except Anthomyidae. Nearly all of Bigot's species in this group are elucidated. There are a few notes also on types of Macquart and Desvoidy.

Brauer, Friedrich, and Bergenstam, J. Edlen von.

Die Zweiflügler des Kaiserlichen Museums zu Wien. Denkschriften d. Kaiserl. Akademie der Wissenschaften, Math.-Naturwiss. Classe. There are seven numbers of this series, of which the first three are by Brauer alone, noticed above. The last four constitute the following series:

Vorarbeiten zu einer Monographie der Muscaria schizometopa (exclusiv Anthomyidae).

IV. Band lvi, pp. 69-180, 11 plates; 1889.

V. Band lviii, pp. 305-446; 1891.

VI. Band lx, pp. 89-240; 1893.

VII. Band lxi, pp. 537-624; 1894.

Many new genera of Tachinidae, Muscidae, Dexiidae and Sarcophagidae. A few North American species. As I have indicated at the beginning of the catalogue of Tachinidae, this work is defective in its conception, in that the characters used for generic definition are often of less than specific value. Nevertheless it is indispensable to the student of these families. It is referred to as "Zweifl. d. Kaiserl. Mus."

Brodie, Wm.

Canadian Galls and their Occupants. Biological Review of Ontario, i, 1894:

I. Pp. 13-15. *Diplosis erigeroni*.

II. Pp. 44-46. *Diplosis helianthi*.

III. Pp. 73-75. *Diplosis thurstoni* and *helianthi-bulla* Walsh.

IV. Pp. 109-111. *Diplosis monardae*.

Brown, Barnum.

Two new Species of Asilids from New Mexico. Kans. Univ. Quarterly, vi, 103, 1897.

Nusa abdominalis and *similis*.

Brues, Chas. T.

Peculiar Tracheal Dilatations in Bittacomorpha clavipes Fabr. Biological Bulletin, i, 155-160, fig., 1900.

A New Species of Dolichopus. Entomological News, xii, 44, 45, fig.; Feb., 1901.

D. sphaeristes, from Texas.

Two New Myrmecophilous genera of aberrant Phoridae from Texas. American Naturalist, xxxv, 337-356, figs. and bibliography; May, 1901.

Commoptera solenopsisidis and *Ecitomyia wheeleri*; notes on related genera and species.

New and little known Guests of the Texan Legionary Ants. American Naturalist, xxxvi, 365-378, figs.; 1902.

Acontistoptera melanderi and *Xainonotum hystrix*.

Notes on the Larvae of some Texas Diptera. Psyche, ix, 351-354, figs.; June, 1902.

Phora epeiræ n. sp., and several species of larvae.

A dixiid Parasite of the Sowbug. Ent. News, xiv, 291; Nov., 1903.

Melanophora roralis Linn.; reared from *Porcellio* sp.

See also Melander and Brues.

Burgess, Edward.

Description of *Oscinis trifolii* and *malvae*, in Report Comr. of Agriculture for 1879, 201, 202.

These are referred to *Agromyza trifolii* and *jucunda* by Coquillett.

Two Interesting American Diptera. Proc. Boston Soc. Nat. Hist., xix, 320-324, 1 plate; Feb. 27, 1878.

Glutops (n. g.) *singularis* and *Epibates osten-sackenii*, n. sp.

Cannon, W. A.

The Gall of the Monterey Pine. American Naturalist, xxv, Oct., 1900, 801-810, figs.

A botanical study of the gall of *Cecidomyia pini-radiata*.

Chagnon, G.

Études Préliminaires sur les Syrphides de la Province de Quebec. Chicotini, Quebec, 1901, 75 pp. Originally published in parts in "Le Naturaliste Canadien," 1901; I quote the separate edition.

No new species.

List of Canadian Diptera. The Entomological Student, Philadelphia. Vol. II, 5-8 and 13-15.

Mostly from Montreal and vicinity; no new species.

Chittenden, F. H.

Some Insects Injurious to the Violet, Rose, and other Ornamental Plants. Bull. 27, n. ser., Division of Entomology, U. S. Department of Agriculture; 114 pp., figs.; 1901.

Life history of *Diplosis violicola* and *Sciara inconstans*.

Some Insects Injurious to Vegetable Crops. Bulletin 33, new series, Division of Entomology, Dept. of Agriculture, 1902. 117 pp., many figs.

Life history of *Psila rosæ*, *Scaptomyza (Drosophila) flavcola*, *adusta* and *graminum*, and *Phorbia fusciceps*.

A Brief Account of the Principal Insect enemies of the Sugar Beet. Bull. 43, Division of Entomology, 1903. 71 pp.

Contains life history of *Pegomyia vicina* and *Phorbia fusciceps*.

Clark, Bracy.

Observations on the Genus *Oestrus*. Transactions of the Linnaean Society, III, 1797.

Oestrus cuniculi, n. sp., from Ga.

An Essay on the Bots of Horses and other Animals. London, 1815, with two plates.

Cuterebra horripilum and *Cephenomyia phobifer* from N. A.

Addenda to Essay on Bots, 1848, with 1 plate.

Cuterebra atrox, from Mexico.

Of the Insect called Oistros by the Ancients, etc. Trans. Linn. Soc., xv, 402, 1826.

Cutcrebra fontinella, from Ill.

Note.—Austen has published notes on some of Clark's species; see his papers.

Cockerell, T. D. A.

Notes on some Species of Gall-Gnats. The Entomologist, London, 1890, 278.

Cecidomyia alticola and *frater*.

Trypetia bigeloviae n. sp. Entomologist's Monthly Magazine, December, 1890, 224.

A Cecid bred from Coccidae. The Entomologist, London, 1892, 280.

Diplosis coccidarum, from Jamaica.

Cecidomyia atriplicis n. sp. American Naturalist, 1895, 766.

New Species of Insects taken on a Trip from the Mesilla Valley to the Sacramento Mts., N. M. Jour. N. Y. Ent. Soc., vi, 201-207, 1898.

Asphondylia neomexicana n. sp.; occurrence of some Diptera, p. 205, footnote.

Diplosis atriplicicola; *Lasioptera willistonii*, *ephedrae*, and *tertia*; *Asphondylia prosopis*. Annals and Mag. Nat. Hist., 1898, 321-331.

Diplosis partheniicola n. sp. The Entomologist, London, July, 1900, 201.

Asphondylia mentzeliae n. sp. The Entomologist, London; Nov., 1900, 302.

A New Cecidomyiid on Gutierrezia. Canadian Entomologist, xxxiii, 23; Jan., 1901.

Asphondylia gutierreziae, New Mexico.

Some Gall-Insects. Canadian Entomologist, xxxiv, 183, 184, 1902.

Lasioptera carbonitens and *ephedricola*, from New Mexico.

Some Insects of the Hudsonian Zone in New Mexico. Psyche, 1902, 346, 347.

No new Diptera.

Comstock, John H.

Report upon Cotton Insects. Department of Agriculture for 1879.

Phora aletiae n. sp. (syn. of *nigriceps*), pp. 209-211. The same abridged in the Report of the Department of Agriculture for 1879, with the addition of *Tachina fraterna* n. sp. (syn. of *Frontina aletiae*), p. 303.

Report of the Department of Agriculture for 1879, pp. 245, 266, 271.

Contains note on *Diastata* sp. mining leaves of corn; *Diplosis catalpae* n. sp., "The Catalpa Pod Diplosis"; and a bibliography of parasitic Cecidomyiidae.

Report on Miscellaneous Insects, in the Report of the Comr. of Agriculture for 1881 and 1882 (pub. Jan., 1893), 135-154.

Life history of *Trypetia (Rhagoletis) pomonella*, *Drosophila ampelophila* and *amana*, and *Sciara (Cecidomyia) ocellaris* O. S.; the last doubtless an error in rearing, as the species can hardly be a *Sciara*.

Comstock, John H. and Anna B.

A Manual for the Study of Insects. Ithaca, 1895. 701 pp., with plates and many figures.

The Diptera are on pp. 413-489. A useful table of families, and brief descriptions of all the lower families, with numerous illustrations. No new species.

Day, Loren T.

Notes on Sciomyzidae, with Descriptions of New Species. *Canadian Entomologist*, XIII, 85-89; April, 1881.

Four new species.

The Species of Odontomyia Found in the United States. *Proceedings of the Academy of Natural Sciences of Philadelphia*, 1882, 74-88.

Nine new species.

DeGeer, Charles.

Mémoires pour servir à l'Histoire des Insectes. Stockholm, 1752-78. 7 vols.

Several American species are described in the 6th volume.

Robineau-Desvoidy, J. B.

Essai sur la Tribu des Culicides. *Mémoires de la Société d'Histoire Naturelle de Paris*, III, 390-413, 1 pl. Paris, 1827.

Five new species from North America.

Essai sur les Myodaires. *Mémoires des Savants étrangers de l'Academie des Sciences de Paris*, vol. II. Paris, 1830, 813 pp.

This massive work contains an original systematic arrangement of all the Calyptrate and part of the Acalyptrate Muscidae. About eighty new North American species are described. Many of the genera, after being ignored for half a century, have of late been adopted and newly defined, especially in Tachinidae. The work is intrinsically valuable, and for its time wonderful. The characters now used for separating the genera of Tachinidae were mostly introduced in this volume. It is very rare and expensive.

Histoire Naturelle des Diptères des Environs de Paris. 2 vols. Paris, 1863. Vol. I, xvi and 1143 pp.; vol. II, 920 pp.

This work was published after Desvoidy's death, and contains some defects due to imperfect editing of his materials. It is devoted almost wholly to European Tachinidae, Dexidae, Sarcophagidae and Muscidae. "Contains short descriptions of a few N. A. Diptera; no new ones."—O. S.

Note.—Osten Sacken, "Record of My Life Work in Entomology," 180-192, 1903, gives an interesting and lucid account of the two main works cited above.

Dimmock, Geo.

Anatomy of the Mouth-Parts and of the Sucking Apparatus of Some Diptera. Boston, 1881; 50 pp., 4 plates.

This is generally recognized as authoritative on the subject.

Doane, R. W.

A New Trypetid of Economic Importance. *Entomological News*, ix, 69-72, 1 pl.; March, 1898.

Rhagoletis ribicola.

Notes on Trypetidae, with Descriptions of New Species. *Journal of the New York Entomological Society*, VII, 177-193, 2 plates; Sept., 1899.

Twenty new species; notes on many others.

Additional Notes on Trypetidae. Journal of the New York Entomological Society, VIII, 47-48; March, 1900.

This is a defense of the preceding, Mr. Coquillett having erroneously relegated some of the species to synonymy.

New North American Tipulidæ. Journal of the New York Entomological Society, VIII, 182-198, 2 plates; Sept., 1900.

Polyangaus n. gen.; 44 new species of *brevipalpi*.

Descriptions of New Tipulidæ. Journal of the New York Entomological Society, IX, 97-127; Sept., 1901.

Fifty-four new species of *Tipula*.

Drury, Drew.

Illustrations of Natural History, wherein are exhibited upwards of two hundred and forty figures of Exotic Insects. London, 1770-82, 3 vols.

A new edition was published by Westwood in 1837, under the title, "Illustrations of Foreign Entomology."

"Eight N. American and West Indian species are figured."—O. S.

Fitch, Asa.

An Essay upon the Wheat-fly and some Species Allied to it. Albany, 1845.

This is the first edition, which was published in the American Quarterly Journal of Agriculture and Science, vol. II, no. 2. It contains the descriptions of *Cecidomyia tritici* Kirby; *Cec. caliptera* n. sp.; *Cec. thoracica* n. sp.; *Cec. tergata* n. sp. A second edition appeared in 1846, in the Transactions of the N. Y. State Agricultural Society, vol. V. A new species, *Cec. cerealis*, is separated in this edition from *C. caliptera*, and full descriptions with figures of both are given.

The Hessian Fly. Albany, 1846 (second edition, 1847). With a plate.

Published originally in the American Journal of Agriculture and Science, vols. IV, V (1846). Reprinted with some additions in the Transactions of the N. Y. State Agricultural Society, vol. VI, pp. 316-376 (1846; in pamphlet form it bears the date of 1847).

Cecidomyia salicis n. sp., described in American Quarterly Journal of Agriculture and Science, vol. 1, p. 203.

Winter Insects of Eastern New York. In the American Journal of Agriculture and Science, vol. v, pp. 274-284. [Reprinted in Lintner's 2d N. Y. Rept., 235-244.]

N. sp.—*Culex hiemalis*, *Chironomus, nivoriundus*, *Trichocera brumalis*.

Survey of Washington County, New York. In the 9th vol. of the Transactions of the N. Y. State Agricultural Society.

Several species occurring in that locality are mentioned in a popular way.

First and Second Report on the Noxious, Beneficial and other Insects of the State of New York. Made to the State Agricultural Society, pursuant to an appropriation for this purpose from the Legislature of the State. Albany; 1856. With 4 plates.

Before the publication of the Second Report, the first had been distributed under the title of First Report, etc.: 1855. This work contains 21 new American Diptera.

Third, fourth and fifth Reports on the Noxious, Beneficial and other Insects of the State of New York, made to the State Agricultural Society, pursuant to an annual appropriation for this purpose from the Legislature of the State. Albany; 1859. With four plates and many wood-cuts.

Cuterebra emasculator n. sp. and several Cecidomyiae.

Sixth, seventh, eighth and ninth Reports, etc., etc. Albany, 1865. With four plates and several wood-cuts.

Contains a new edition of the papers on *Cecid. tritici* and *destructor*.

All these reports appeared successively in the Transactions of the N. Y. State Agricultural Society, and were collected and issued afterwards as separate volumes: Volume 1, containing Reports 1 and 2; Vol. II, Reports 3-5; Vol. III, Reports 6-9. Each volume has a title-page, as given above, and a complete index of the contents. In the first and third volumes the pagination runs through the whole volume; in the second volume, a new pagination begins with every report, but at the same time, the species successively discussed are numbered and these numbers run through the whole volume. For this reason, in quoting the second volume, I had to give the number of the species referred to, while in quoting the other two volumes, I give the page.—Dr. Fitch's following Reports, which I have seen up to the 12th (1867), do not contain any new species of N. A. Diptera.

Note.—The above account of Fitch's writings is quoted bodily from Osten Sacken's Catalogue. It remains to add that the Reports were continued to 1872. Lintner, in his First N. Y. Report, 1882, pp. 291-325, gives a fuller account of the writings of Fitch. As I have copied all of Osten Sacken's references, I necessarily quote his editions, although the others were often earlier.

Trupanea apivora (syn. *Promachus fitchii*) is inadvertently omitted above. It is described in the 9th Report.

Fletcher, James.

Reports of the Entomologist and Botanist, Central Experiment Farm, Canada Department of Agriculture.

A number of short references to the occurrence and habits of Diptera of economic importance are to be found in this series; the report for 1897 has a somewhat longer article on *Psila rosea*, "The Carrot Rust-Fly," 196-198, figs.

Contents of the preceding, by number (all Mexican and Central American) :

No. 84, *Ditomyia zonata* and *mexicana*.

No. 102, Diagnoses of twelve Stratiomydæ.

No. 108, *Berismyia*, *Rhopalosyrphus*, *Omegasyrphus*, *Megametopon* n. gen.

No. 117, *Camerania* n. g. (see *Volucella macrocephala*).

No. 118, Notes on *Rhopalosyrphus* and *Omegasyrphus*.

No. 123, diagnoses of 31 species of Syrphidæ.

No. 132 (two numbers exactly alike in title, but with different contents),
30 diagnoses of Syrphidæ and Conopidæ.

No. 147, diagnoses of 47 species of Calypterate; 4 new genera.

No. 158, seven genera, many species, of *Cyclorrhapha*.

No. 224, *Pityocera festa*.

No. 276, syn. of *Pityocera festa* with *Dicrania cervus* WIED.

The preceding numbers, except the last two, are supposed to be superseded by the following:

Ditteri del Messico. Memoria della Reale Accademia delle Scienze di Torino, Serie II:

Parte I. Stratiomydæ-Syrphidæ. Tom. XLIII, 72 pp., 1 plate; 1892.

Parte II. Syrphidæ-Conopidæ-Pipunculidæ. XLIII, 79 pp., 1 pl.; 1892.

Parte III. Muscidæ Calypteratæ. XLIV, 76 pp., 1 pl.; 1893.

Parte IV. Calypteratæ and Acalypteratæ. XLV, 73 pp., 1 pl.; 1895.

Many Mexican genera and species. I am unable to give the original pagination.

Giles, Geo. M.

A Handbook of Gnats or Mosquitoes. Second edition, London, 1902. 530 pp.; many plates and figures.

The systematic part of this is practically an abridgement of Theobald's Monograph, and contains descriptions of most of the North American species—all that were known at that time.

The first edition was a different book, with less systematic work. It contained one new North American species, *Culex willistonii*, which Coquillett has since referred to his *tarsalis*.

Gillette, C. P.

A New Cecidomyiid Infesting Box Elder. Psyche, 1890, 392, 393.
Cecidomyia negundinis.

Harrington, W. Hague.

Occupants of the Galls of *Eurosta solidaginis* Fitch. Canadian Entomologist, xxvii, 197-198, 1895.

No new species.

Harris, Thaddeus W.

"Catalogue of the Insects of Massachusetts. In Prof. Hitchcock's Report on the Geology, Botany and Zoology of Massachusetts.

Professor Hitchcock's Report had two editions; in the first (1833), Dr. Harris mentioned only the generic names of the insects, adding the number of species belonging to each genus. In the second edition (1835), the specific names are also given; many of them are mere collection names, never having been published.

"A Treatise on some of the Insects of New England, which are injurious to Vegetation. Second edition. Boston, 1852.

The first edition of this work was published in 1841, under the title of A Report on the Insects of Massachusetts, Injurious to Vegetation. The second edition contains many additions.

"A Treatise on Some of the Insects Injurious to Vegetation. Third edition. Boston, 1862. With 8 plates and 278 wood-cuts.

Was published at the expense of the Commonwealth of Massachusetts and is provided with notes by different authors: these on the Diptera are by C. R. Osten Sacken. The quotations in the present volume are from this edition.

"Entomological Correspondence. Edited by Samuel Scudder. Boston, 1869.

Contains on pp. 335, 336, descriptions of *Musca harpyia* HARRIS (syn. *Musca domestica* L.) and *Musca familiaris* HARRIS (apparently the same as the European *Pollenia rudis*). Quoted from O. S.

Harris, H. F.

The Eggs of *Psorophora ciliata*. Entomological News, xiv, 232, 233; 1903.

Hart, Chas. A.

On the Entomology of the Illinois River and Adjacent Waters. First Paper.

Bulletin of the Illinois State Laboratory of Natural History, iv, Article vi, pp. 149-280, with 14 plates. The Diptera extend from p. 184 to p. 270, with 10 plates. Springfield, Ill., 1895.

Contains a large amount of valuable and interesting information about the aquatic dipterous larvae, many species being described and figured. No new species.

Harvey, F. L.

The Currant Fly. Bulletin 35, Maine Experiment Station; May, 1897. 8 pp. and plate.

Epochra canadensis LOEW, habits, etc.

Report Entomologist and Botanist, in the Annual Report Maine Experiment Station, 1889, 148-256, 1 plate and 11 figs.

Full life history of *Trypetia (Rhagoletis) pomonella*.

Hausmann, J. F. L.

Entomologische Bemerkungen. Braunschweig, 1709.

Syphus trifasciatus n. sp. (syn. of *Milicia ornata*). According to Hagen, Hausmann, who afterward became a professor in Göttingen, was only sixteen years old at the time of this publication.

Herrera, A. L.

El Gusano de la Fruta. Boletin de la Comision de Parasitologia Agricola, 1. No. 1. Mexico City, 1900.

A pamphlet of thirty pages on *Trypetia ludens*, the fruit-fly of the orange; figures and account of damage, etc.

Herrick, A.

Corethra appendiculata n. sp., in Minnesota Geol. and Nat. Hist. Survey, 1884, 10, pl. v. Larva only, and very vaguely described. (Data from Johannsen.)

Hine, J. S.

Sciara inconstans Fitch—Reared from Carnations. Entomological News, x, 201, 202, figs.; Sept., 1899.

Pangonia chrysocoma O. S. Entomological News, xi, 392; March, 1900.
Synonymy of *Goniops hippoboscoides*.

Two New Species of Tabanidae. Canadian Entomologist, xxxii, 247; Aug., 1900.

Tabanus pruiniosus (afterward changed to *ohioensis*) and *thoracicus*.

Collecting Tabanidae. Ohio Naturalist, ii, 167; Dec., 1901.

Habits of adults in several species.

Observations on Insects. Ohio Naturalist, ii, 169; Dec., 1901.

Notes on habits of *Agromyza setosa* Lw., *Bibio albipennis* and *Chrysopila ornata*.

New or Little-Known Diptera. Ohio Naturalist, ii, 228–230; March, 1902.

Pachygaster maculicornis and *Phorantha bridwelli*; notes on several other species.

The genus Pedicia, with one new Species. Ohio Naturalist, iii, 416, 417; April, 1903.

P. magnifica.

Some Diptera from Arizona. Canadian Entomologist, xxxv, 244–246; Sept., 1903.

Tabanus hyalinipennis, *Myiolepta aurinota*; notes on three described species.

Tabanidae of Ohio. Ohio Academy of Sciences, Special Papers, No. 5, 1903.

Also published as University Bulletin No. 19, series 7, Ohio State University. 63 pp., 2 plates.

Chrysops brunneus and *sackeni*; all the Ohio species redescribed.

On the life history of *Tabanus vivax*. Ohio Naturalist, iv, Nov., 1903, 2 pp.

Holmgren, A. E.

Insekten fra Nordgrönland, samlade af Prof. A. E. Nordenkiöld år 1870. Kongl. Vetenskap. Förhandlningar, 1872, No. 6, pp. 97–105.

Nine new species; thirty-nine in all.

Holstein, G. W.

Notes on *Hypoderma lineata* in Texas. Entomological News, iv, 299, 300; Nov., 1893.

Hood, Lewis E.

The Leptidae and Bombylidæ of the White Mts. Psyche, vi, 283, 284; July, 1892.

Occurrence of about twenty species, with notes; none new.

Hopkins, A. D.

Notes on the Habits of Certain Mycetophilids, with Description of *Epidapus scabiei* n. sp. Proceedings of the Entomological Society of Washington, iii, 149–159, figs.; 1895.

Forms of So-Called Potato Scab Caused by Insects. Special Bulletin 2, West Virginia Experiment Station, 97-111, 1895; many figs.

Potato scab produced by *Epidapus scabiei*.

The Hessian Fly in West Virginia. Bulletin 67, West Virginia Experiment Station, Aug., 1900; 14 pp., 2 plates and map.

Studies in the life history of *Mayetiola destructor*.

Hough, Garry deN.

Two New American Species of Cynomyia. Entomological News, ix, 105-111, figs.; May, 1898.

C. americana and *elongata*.

A Third American Species of Cynomyia. Entomological News, ix, 165, 166, figs.; Sept., 1898.

C. hirta.

The Muscidae Collected by Dr. A. Donaldson Smith in Somali Land. Proceedings of the Academy of Natural Sciences of Philadelphia, 1898, 165-167, figs.

An important discussion of chætotaxy; no new North American species.

Parasitic Influence on Melanoplus. By S. J. Hunter. Kansas University Quarterly, vii, 207-210, figs.; Oct., 1898.

Description of *Sarcophaga hunteri* n. sp., by Dr. Hough.

Some North American Genera of Calliphorinae. Entomological News, x, 62-66; March, 1899.

Genera defined; no new species.

Some Muscine of North America. Biological Bulletin 1, 19-33, figs.; 1899.

Muscina texana and *aurantiaca*; list of genera and species, etc.

Studies in Diptera Cyclorrhapha. I. The Pipunculidae of the United States. Proceedings of the Boston Society of Natural History, xxix, 77-86; July, 1899.

Pipunculus atlanticus, *similis* and *flavomaculata*.

Synopsis of the Calliphorinae of the United States. Zoological Bulletin, ii, 283-290, figs.; 1899.

Chrysomyia wheeleri, *Calliphora coloradensis* and *latifrons*, *Lucilia pilatci*.

South American Muscidae in the Collection of S. W. Williston. Kansas University Quarterly, ix, 203-232, 2 plates; July, 1900.

A few which occur also in Mexico and the United States are carefully redescribed.

Howard, Leland O.

Notes on a Simulium Common at Ithaca, N. Y. Insect Life, i, 99-101; Oct., 1888.

Life history; species not named, but probably *pictipes* HAGEN.

An Ortalid Fly Injuring Growing Cereals. Insect Life, vii, 352-354, figs.; March, 1895.

Chætopsis anca WIED.; life history.

The Beet-Leaf Pegomyia. Insect Life, vii, 379-381, figs.; July, 1895.

Pegomyia vicina LINTNER; life history.

Mosquitoes and Fleas. Circular No. 13, second series, Division of Entomology, Department of Agriculture; 6 pp. of general information; Feb. 1, 1896.

The Principal Household Insects of the United States. Bulletin 4, new series, Division of Entomology, Department of Agriculture, 130 pp.; 1896. By Howard and Marlatt; several articles on common household Diptera by Howard.

Further Notes on the House-fly. Bulletin No. 10, new series, Division of Entomology, Department of Agriculture, pp. 63-65; 1898.

Treatment of manure to kill the larvae.

Notes on House-flies and Mosquitoes. Bulletin 17, new series, Division of Entomology, Department of Agriculture; pp. 55, 56; 1898.

How to distinguish the Different Mosquitoes of North America. Circular No. 40, second series, Division of Entomology, Department of Agriculture; 8 pp. The tables are by Coquillett.

Notes on the Mosquitoes of the United States. Bulletin 25, new series, Division of Entomology, Department of Agriculture, 70 pp.; 1900.

Remarks on *Psorophora ciliata*, with Notes on its Early Stages. Canadian Entomologist, XXXII, 353-357, figs.; Dec., 1900.

Life history, well illustrated.

A contribution to the Study of the Fauna of Human Excrement. Washington Academy of Sciences, II, 541-604, many illustrations; Dec. 28, 1900.

Life histories of many flies living in excrement; very valuable. Partially summarized in Bulletin 30, n. ser., Div. of Ent., 1901, 39-45.

Diptera Bred from Cow-Manure. Canadian Entomologist, XXXIII, 42-44; Feb., 1901.

A list of twenty species, none new.

Mosquitoes; how they live, how they carry Disease, etc. New York, 1901, with many illustrations.

Transformations, habits, etc.; table and list of species by Coquillett.

Hunter, W. D.

The Dipterous Enemies of Domestic Animals and Man. Nebraska State Board of Agriculture, 1895, 288-306.

Popular account; no new species.

A Contribution to the Knowledge of North American Syrphidæ. I. Canadian Entomologist, XXVII, 87-101; April, 1896.

Four new species; many little known species redescribed.

A New Species of Tropidia, and Note on the Generic Position of *Melanostoma rufipes* Will. Entomological News, VII, 215, 216; Sept., 1896.

T. nigricornis, changed on p. 308 to *montana*.

A Summary of the Members of the Genus *Chilosia* Meig. in North America, with Descriptions of New Species. Canadian Entomologist, XXVIII, 227-233; Sept., 1896.

Ch. signatistcta, *cyanæa* and *aldrichi*; table and list of species.

A Contribution to the Knowledge of North American Syrphidæ. II. Canadian Entomologist, XXIX, 121-144, 1 plate; June, 1897.

Pyritis n. gen.; twelve new species.

Hunter, Samuel J.

Parasitic Influence on *Melanoplus*. Kansas University Quarterly, VII, 205-210; Oct., 1898.

Notes on *Sarcophaga cimbicis* TOWNSEND, and description by Dr. Hough of *Sarcophaga hunteri*.

Alfalfa, Grasshoppers, Bees. Bulletin of the Entomological Department of the University of Kansas, 1898; 152 pp.

The part on Diptera, pp. 32-37, is about the same as in the preceding.

Illiger, J. C. W.

Neue Insekten. Magazin für Insektenkunde, I, 206; 1802.

Midas fulvifrons n. sp., from Georgia.

Jaennicke, F.

Neue Exotische Dipteren. Abhandlungen der Senckenburgischen Gesellschaft, VI, 311-407, 2 plates; 1867. Also published separately, 100 pp., 4to, Frankfurt, 1867. The pagination of the latter is used by Osten Sacken and repeated here.

Many new exotic Diptera, of which thirty-four are from Mexico and the United States.

Johannsen, Oskar A.

Notes on Some Adirondack Diptera Collected by MacGillivray and Houghton. Entomological News, XIV, 14-17; Jan., 1903.

Sciophila pulchra n. sp.; notes on several other species.

Aquatic Nematocerous Diptera. In Bulletin 68, New York State Museum, 328-448, 19 plates; Aug., 1903.

A very valuable work, monographic in the Simuliidæ, and containing tables for determining larva, etc., in several families. *Pelorempis* (n. gen.) *americana*, *Corethra albipes*, *Thalassomyia obscura*, and *Dixa modesta* (the last a syn. of *D. clavula* WILL.—Ent. News, XIV, 302).

Johnson, Chas. W.

The Puparium of *Ceria signifera*. Entomological News, IV, 91; March, 1893.

List of Diptera of Jamaica, with Descriptions of New Species. Proceedings of the Academy of Natural Sciences of Philadelphia, 1894, 271-281.

About fifty species recognized; new are *Nemotelus flavicornis*, *Chrysopila jamaicensis*, *Calobata pluritica*, and *Leptogaster longipes* (the last changed to *clavipes*, Ent. News, VIII, 120).

A Review of the Stratiomyidæ and Odontomyidæ of North America. Transactions of the American Entomological Society, XXII, 227-278, 2 plates; July, 1895.

Seven new species; the old ones are redescribed or former descriptions quoted.

Diptera of Florida. Proceedings of the Academy of Natural Sciences of Philadelphia, 1895, 303-340.

504 species recognized, six new; also several new, described by Coquillett.

Some Notes and Descriptions of New Leptidæ. Entomological News, VIII, 117-120, figs.; May, 1897.

Chrysopila griffithi, *Symphoromyia hirta*, new; other species redesc.

Notes and Descriptions of New Syrphidæ from Mt. St. Elias, Alaska. Entomological News, IX, 17, 18; Jan., 1898.

Syrphus bryantii and *Melanostoma glacialis*; notes on four others.

Catalogue of the Diptera of New Jersey. Supplement to 27th Annual Report of New Jersey State Board of Agriculture, 1899, pp. 615-699.

About 1200 species recorded from New Jersey, mostly with exact localities and many with dates; many species figured; no new ones. This was published as a part of John B. Smith's Catalogue of the Insects of New Jersey, and the occurrence of these species is cited by me as "N. J.—Smith Cat."

Notes and Descriptions of Seven New Species and One New Genus of Diptera. Entomological News, xi, 323–328; Jan., 1900.

Scpsisoma n. g.

New North American Ortalidae. Canadian Entomologist, xxxii, 246, 247; Aug., 1900.

Pyrgota chagnoni, *Stenopterina bicolor*, *Rivellia floridana*.

Variation in the Venation of *Amalopis inconstans* O. S. Entomological News, xii, 305–307, figs.; Dec., 1901.

 Catalogus Dipterorum hucusque Descriptorum. Museum Nationale Hungaricum. Budapestini; typis G. Wesselényi.
 Vol. I. 1902. Sciaridae to Rhyphidae.
 Vol. II. 1902. Cecidomyiidae to Cylindrotomidae.
Note.—The above catalogues contain references to the North American species up to the following dates respectively: Jan. 1, 1890; Jan. 1, 1901; Jan. 1, 1900, and Jan. 1, 1901.

Kincaid, Trevor.

The Psychodidae of Washington. Entomological News, viii, 143-146; June, 1897.

Psychoda pacifica, elegans, olympia.

Psychodidae of the Pacific Coast. Entomological News, x, 30-37, 1 plate; Feb., 1899.

Ten new species; table of genera.

Notes on American Psychodidae. Entomological News, xii, 193-196, 1 plate; Sept., 1901.

Pericoma ocellaris var. *americana*, and *P. californica*.

Kirby, William.

Fauna Boreali-Americana; or the Zoology of the Northern Parts of British North America, by J. Richardson, assisted by W. Swainson and Will. Kirby. London; 1829-37; 4 vols. The fourth volume contains the Diptera, which are by Kirby, nine in number. The descriptions are reprinted in Canadian Entomologist, xiii, 164-169, 1881.

Kirkpatrick, J.

The Army Worm. Ohio Agricultural Report for 1861.

Exorista leucaniae and *osten sackenii*, parasites of the army worm; both are supposed to be synonyms of *Wintheimia quadripustulata*.

Kowarz, Ferdinand.

Phytomyza chrysanthemi, in Lintner's 7th New York Report, 243; 1891.

Lamarck, J. B.

Histoire Naturelle des Animaux sans Vertebrés, etc., 1ere ed.; 7 vols. Paris, 1815-22. Also 2ieme ed. Ibid., 1835-45.

"The insects form the third volume of the first, and the fourth of the second edition. I have quoted the first edition. Some typical forms only of American insects are mentioned in this work, and no new species described."—O. S.

Latreille, P. A.

Histoire Naturelle, générale et particulière des Crustacés et des Insectes; 14 vols. Paris, 1802-04. (Diptera in vols. III and XIV; 1802 and 1804.)

Genera Crustaceorum et Insectorum, etc.; 4 vols. Paris; 1806-7-9.

Both of these works "contain the mention or description of some typical forms from North America, but no new species." They are also important for genera.

Leach, W. E.

On the Genera and Species of Eproboscideous Insects. In the Wernerian Transaction, II, Edinburgh, 1817.

Olfersia americana and *Ornithomyia erythrocephala* from N. A.

LeBaron, William.

Second Annual Report on the Noxious Insects of the State of Illinois, 1872.

Tachina (Exorista) phycitae, which has been referred by Coquillett to *Exorista pyste* WALK.

Linné, Carl Von.

Systema Naturae per Regna Tria Naturae Secundum Classes, Ordines, Genera, etc., 10th edition, 1758.

Contains descriptions of sixteen species referred to America, some of which are South American.

Amenitates Academicæ, etc., 7 vols., 1749-1769.

Contains *Asilus astuans*, from Pennsylvania.

Lintner, J. A.

Reports of the New York State Entomologist. Articles on Diptera, chiefly biological and economic, almost always with bibliography, occur as follows:

First Report (for 1882, issued 1883).

On Some Species of Anthomyidae, 168-202, with figs.

Notice of Some Anthomyians Mining Beet Leaves, 203-211, figs.

Chortophila betarum and *Pegomyia vicina* n. sp.

Mallota posticata, 211-216, figs.

Drosophila ampelophila, 216-221, figs.

Meromyza americana, 221-227, figs.

Second Report, 1885.

The Emasculating Bot-fly, 45, 46.

Bibio albipennis, *Microdon globosus*, *Trypetia pomonella*, 110-125, figs.

Fourth Report, 1888.

Cecidomyia balsamicola n. sp., and Its Gall, 60-63, figs.

Lasioptera vitis O. S., 63-67, figs.

Chloropisca prolifica O. S. n. sp., and Its Winter Gathering in Dwellings, 67-72, fig.

Phytomyza lateralis FALL., 73-80, figs. The name is changed in 7th Report to *Ph. chrysanthemi* n. sp. Kowarz.

Fifth Report, 1889.

Hæmatobia serrata DESV., 220-227, fig.

Sixth Report, 1889.

Hypodermia bovis DEG., 111-116, figs. The species is now considered to be *lincata* Vill.

Drosophila sp. (The Flour-paste Fly), 116, 117.

Seventh Report, 1891.

Helophilus latifrons LOEW, 228-234, figs.

Chloropisca prolifica O. S., 234-241, figs.

Phytomyza chrysanthemi KOWARZ n. sp., 242-246, figs.

Cecidomyia balsamicola, 307-310.

Cecidomyia sp., 308-310.

Eighth Report, 1893.

Diplosis pyrivora RILEY, 140-151, figs.

Exechia sp., a Fungus Gnat, 172.

The Cow-Horn Fly in New York, 192-197.

The Apple Maggot, 245-249.

Ninth Report, 1893.

Pollenia rudis, the Cluster Fly, 309-314, figs.

Tenth Report, 1895 (with index to all preceding).

Diplosis pyrivora RILEY, 386, 387, fig.

Notes on *Sciara*, 387-399, figs. and plate.

S. coprophila and *caldaria* n. sp.

Phora agaraci n. sp., 399, 406, plate and figs.

Eleventh Report, 1896.

The Birch-seed Midge, *Cecidomyia betulæ* Winn., 162-165, plate.

Diplosis cucumeris n. sp., 165-168, plate.

Diplosis setigera n. sp., 168-170, plate.

Anthomyia sp.? The Raspberry-Cane Maggot, 170-172. Afterward described as *Phorbia rubivora* Coq.

Twelfth Report, 1897.

Additional Notes on *Sciara*, by E. P. Felt, 223-228, plate.

Five n. sp.

Phora albidihalteris n. sp., by E. P. Felt, 228, 229.

Piophila casei LINN., 229-234, figs.

A Cecidomyiid in Choke-cherries (undet.), 313, note.

Lochhead, William.

The Hessian Fly in Ontario. Bulletin 116, Ontario Agricultural College and Experiment Station, 1901; 16 pp., figs., etc.

Loew, Hermann.

Beschreibungen einiger neuen Tipularia terricola. Linnaea Entomologica, v, 385-406, 1851.

Aporosa rufescens and *virescens*, *Toxorhina fragilis*, from West Indies.

Bemerkungen über die Gattung Beris. Stett. Entomol. Zeit., vii, 1846, in four instalments.

Several North American species mentioned; no new ones.

Helophilus. Stett. Entomol. Zeit., vii, 1846, in three instalments.

Monograph of the genus; *H. glacialis* n. sp., from Labrador.

Chauna genus novum. Stett. Entomol. Zeit., viii, 370; 1847.

Chauna variabilis, from Cuba.

Über *Tetanocera stictica* Fab. und ihre nächsten Verwandten. Stett. Ent. Zeit., viii, 114-124; 1847.

T. flavescens, from Carolina.

Über *Tetanocera ferruginea* Meig., und die ihr verwandten Arten. Stett. Ent. Zeit., viii, 194-202; 1847.

T. plumosa, from Sitka.

Bemerkungen über die Familie der Asiliden. Programme der Realschule zu Meseritz, 1850; pp. 1-22.

Dasypteron anthracinus, from Mexico.

Ceria and *Conops*. In the Series, Neue Beiträge zur Kenntniss der Dipteren, which were originally printed from year to year in the Program der Realschule zu Meseritz, and afterwards by Mittler, in Berlin. Beitrag i, 1853, 38 pp.

Ceria pictula, *arictis*, and *signifera*; *Conops genualis*, *bulbirostris*, and *castanoptera*.

Neue Dipteren. Neue Beitr., ii, 1854, 24 pp.

Pyrgota millepuncta (syn. of *P. valida* HARRIS).

Bombylius. Neue Beitr., iii, 1855, 52 pp.

Monograph of the genus in Europe; no new N. A. species, but some synonymous references.

Dipterologische Notizen. Neue amerikanische Dolichopoden. Wiener Entomol. Monatschrift, i, 37, 1857.

Lyoncurus cæruleoescens and *Plagioneurus univittatus*.

Excursion nach dem Neusiedler See. Neue Beitr., iv, 1856, 58 pp.

"On p. 18 several European species also occurring in N. A. are mentioned, but a part of these statements is based on erroneous data about the locality. *Helophilus pendulus*, *versicolor*, *florculus*, and *Chrysotoxum bicinctum* have never, as yet, been found in N. America."—O. S.

Zur Kenntniss der Europäischen Tabanus-Arten. Verhandlungen der Zool.-Bot. Gesellsch. zu Wien, 1858, 573-612.

Tabanus septentrionalis, from Labrador.

Über einige Fliegengattungen. Berlin Entomol. Zeitschr., II, 101-122, 1 plate; 1858.

Plecia longipes, from New Orleans.

Die nordamerikanische Arten der Gattungen Tetanocera and Sepedon. Wiener Entomol. Monatschr., III, 289-300, 1859.

Several species, afterward embodied in Monograph I.

Diptera americana ab Osten-Sackenio collecta, decas prima. Wiener Entomol. Monatschr., IV, 79-84, 1860.

Ten new species; all reproduced in later publications, except *Clinocera maculata* and *conjuncta*.

Diptera aliquot in insula Cuba collecta. Wiener Entomol. Monatschrift, V, 33-43, 1861.

Twenty new species.

Die nordamerikanischen Dolichopoden. Neue Beitr., VIII, 1861, 100 pp.

An extensive work, afterward embodied in Monograph II.

Die amerikanischen Ulidina. Berl. Entomol. Zeitschr., XI, 283-326, 1 plate; 1867.

Several new genera and species, which were all later embodied in Monograph III.

Monographs of the Diptera of North America, vols. I, II, III, with 11 plates. Washington, Smithsonian Miscellaneous Collections.

Vol. I, 1862.—General introduction, Trypetidae, Sciomyzidae, Ephydridae, and Cecidomyiidae (the last by Osten Sacken.)

Vol. II, 1864.—Dolichopodidae.

Vol. III, 1872.—Ortalidae and additions to Trypetidae.

Diptera americæ septentrionalis indigena. In the Berliner Entomol. Zeitsch. Centuria I, 1861; II in 1862; III and IV in 1863; V in 1864; VI in 1865; VII in 1866; VIII and IX in 1869; X in 1872. Also published separately, in two volumes.

One thousand North American Diptera! Referred to in the present work as "Loew, Cent."

Diptera Common to Europe and America. Silliman's American Journal of Science and Arts, XXXVII, 317; May, 1864. This list is appended to a translation of Loew's lecture on "The Diptera of the Amber Fauna." Eighty-five species are mentioned as common to the two continents, most of them not previously reported from North America. The work is referred to herein as "Silliman's Jour."

Bemerkungen über die von Hn. Van der Wulp in der Zeitsch. d. Niederländ. Entomol. Ges. für 1867 publicirten N. A. Dipteren. Zeitsch. f. Ges. Naturwissenschaften, XXXVI, 113-120, 1870.

Remarks about the synonymy and generic position of the species in Van der Wulp's article.

Über die Arten der Gattung Sphyracephala Say. Zeitsch. f. Ges. Naturwiss., XLII, 101, 1873.

Remarks on *Sphyracephala brevicornis*.

Neue nordamerikanische Dasypogonina. Berliner Entomologische Zeitschr., XVIII, 353-377, 1874.

Fourteen new species.

Neue nordamerikanische Dipteren. Berliner Entom. Zeitsch., xviii. 378-384.
Six new species.

Beschreibungen neuer amerikanischen Dipteren. Zeitsch. f. Ges. Naturwiss.,
xlviii, 317-340, 1876.

Seventeen new species.

Revision der Blepharoceridae. Schles. Zeitschr. f. Entomol., Neue Folge, vi.
Breslau, 1877.

The description of *Bibiocephala grandis* is reproduced here, in German.

Neue nordamerikanischen Ephydrinen. Zeitsch. f. Gesamten Naturwiss.,
l. 192-203; March and April, 1878.

Fourteen new species.

Table of North American Species of Pachyrhina. Verh. Zool.-Bot. Ges.,
1879. 513-516.

No new species.

✓ *Note.*—There are many other important papers of Loew, which should be
consulted. He rarely wrote anything unimportant. The above, however,
are all in which the North American fauna is directly referred to.

Long, Wm. H., Jr.

New Species of Ceratopogon. Biological Bulletin, iii, May and June, 1902.
C. brumalis, stenammatis, texanus, wheeleri.

Lugger, Otto.

Parasites of Man and the Domesticated Animals, in Second Report of the
State Entomologist of Minnesota, 1896 (published 1897).

Pages 145-182 and 209-230 are devoted to Diptera; *Simulium minutum,*
irritatum and *tribulatum* are named and figured, but not described.

Lundbeck, Will.

Entom. Unters. i Vest-Grenl. Medd. om Grenl., Heft vii, 1893.

A brief article, not seen by me; appears to be superseded by the following.

Diptera Grönlandica. I. Videnskabelige Meddelelser Naturhistoriske Forening
i Kjöbenhavn, 1898, 236-314, 2 plates. II. Ibid., 1900, 281-316, figs.

A number of new species; the old faunal lists of Staeger, Holmgren,
and Schiödte are carefully reviewed, and the species elucidated.

Lynch Arribalzaga, Felix.

Dipterología Argentina. Culicidae. Revista del Museo de la Plata, i, 345-413,
with five plates (two colored); 1891.

Dipterología Argentina. Syrphidae. Anales de la Sociedad científica Argentina,
xxxii, xxxiii, and xxxiv, in instalments; 1891-1893.

Dipterología Argentina. Mycetophilidae. Boletín de la Academia Nacional
de Ciencias, xii, 377-436 and 471-483; 1892.

El Genero Sapromyza en America. Anales de la Sociedad científica Argentina,
xxxiv, 253-301; 1893.

Important on account of the large number of tropical species, many of
which are found also in Mexico and Central America, or in the West
Indies.

McGillivray, A. D. and Houghton, C. O.

A List of Insects taken in the Adirondacks, N. Y. Diptera in Entomological
News, xiv, 12, 13; Jan., 1903.

About ninety species, determined by Johannsen. The exact locality is
Axton, N. Y.

Macquart, Jean.

Histoire Naturelle des Diptères. 2 vols., with 24 col. pl. Paris, 1834, 1835.

Forms part of the Suites à Buffon, published by Roret.

The species are mostly European; there are a few scattered throughout from North America.

Diptères Nouveaux ou peu Connus. Two volumes in five parts, and five supplements in six parts. Mémoires de la Société des Sciences et des Arts de Lille.

Vol.	I, part 1	1838	pp. 9-225	25 plates.
	I, " 2	1838	121-323	14 "
	II, " 1	1841	282-414	21 "
	II, " 2	1842	63-200	22 "
	II, " 3	1843	162-460	36 "
Suppl.	I,	1845	133-364	20 "
	II,	1847	21-120	6 "
	III,	1847	161-240	7 "
	IV, part 1	1850	309-479	14 "
	IV, " 2	1851	134-294	14 "
	V,	1855	25-156	7 "

This set contains an immense amount of material from North America, especially the larger flies of the southern regions. I give the dates of actual publication according to Hagen, although I observe that they do not agree exactly with Osten Sacken, nor with those penciled on my own set. The nominal date of publication was one year earlier, except with the first, second and eighth numbers. The work was also published separately, with different pagination, and this was used by Osten Sacken in his Catalogue; it is therefore continued by me. The parts without exception are indexed, so that any difficulty about the pages will readily be overcome.

Notice sur une nouveau Genre de la Famille des Pupipares, etc. Annales Soc. ent. de France, 1852, 331-333, pl. iv, f. 4.

Megistopoda pilatei, from Mexico and Cuba.

Notice sur une nouvelle Espèce d'Aricie. Annales Soc. ent. de France, 1853, 675, pl. xx, f. 2.

Aricia pici, from San Domingo.

Marlatt, C. L.

Report of a Trip to Investigate Buffalo Gnats. Insect Life, II, 7-11; July, 1889.

Notes on breeding habits of *Simulium meridionale*.

The Xanthium Trypetæ. Insect Life, III, 312, 313, figs.; April, 1891.

Life history of *Euaresta aequalis*.

The Ox Warble. Circular No. 25, sec. ser., Div. of Entomology; July, 1897, 10 pp., figs.

Hypoderma lincata Vill.

The Principal Insect Enemies of Growing Wheat. Farmers' Bulletin No. 132, Division of Entomology, Dept. of Agriculture, 40 pp., 1901, figs.

Life history of *Mayetiola destructor*, *Contarinia tritici*, and *Meromyza americana*.

Marten, John.

New Tabanidae. Canadian Entomologist, xv, 110-112; June, 1883.

Tabanus allynii, *tetricus*, *frenchii*, *susurrus*.

Description of Asphondylia helianthi-globulus. *Psyche*, Sept.-Oct., 1888, 102.

Description of a New Species of Gall-making Diptera. *Bulletin of the Ohio Experiment Station, Technical series*, 1, No. 3, 155, 156, 1893.
Lasioptera muhlenbergiae.

Matas, Dr. R.

A Man-Infesting Bot. *New Orleans*, 1887; privately printed. Reviewed in *Ins. Life*, 1, 76-80, figs.

An undetermined species, supposed to be a *Dermatobia*.

Meade, R. H.

List of North American Anthomyidae. *Canadian Entomologist*, XIII, 43-51, 1881.

No new species; several European recognized, with more or less doubt.

List of North American Sarcophagidae. *Canadian Entomologist*, XIII, 146-150, 1881.

Notes on a number of species; none new.

Meigen, J. W.

Systematische Beschreibung der bekannten europäischen zweiflügeligen Insekten. 7 vols., Achen and Hamm, 1818-1838.

The work contains only European species, but many are common to both continents.

Melander, Axel L.

A Decade of Dolichopodidae. *Canadian Entomologist*, XXXII, 134-144, figs.; May, 1900.

Ten new species.

Gynandromorphism in a New Species of *Hilara*. *Psyche*, IX, 213-215, figs.; June, 1901.

Hilara wheeleri.

Notes on the Acroceridae. *Entomological News*, XIII, 178-181, fig.; June, 1902.

Notes on twelve species; *Opscius agalena* n. sp., but according to Adams this is a synonym of *Op. pterodontinus* O. S.

Monograph of the North American Empididae. Part I. *Transactions of the American Entomological Society*, XXVIII, 195-367, five plates; July-Oct., 1902.

Many new species and several genera. Includes all the family except the genus *Rhamphomyia* "in its wide sense."

An Interesting New Chrysotus. *Entomological News*, XIV, 72, fig.; March, 1903.

C. philtrum.

A Review of the North American Species of Nemotelus. *Psyche*, 1903, Oct.-Dec., pp. 171-183, 1 plate.

arator, *bruesii*, *trinotatus*, *wheeleri* and *bellulus*, new.

See also Wheeler and Melander.

Melander, A. L. and Brues, C. T.

New Species of Hygrocelenthus and Dolichopus. *Biological Bulletin*, 1, 123-148, many figures; 1900.

Fifteen new species; several others redescribed.

Guests and Parasites of the Burrowing Bee *Halictus*. *Biological Bulletin*, V, 1-27, figs.; June, 1903.

Ceratopogon hollensis; Phora cata, rostrata and halictorum; Stethopathus occidentalis.

Mik, Josef.

Ueber die dipterologischen Referate in den Jahrgängen 1882 bis inclusive 1890 der Wiener Entomologischen Zeitung. Wien. Entomol. Zeitung, ix, 281-308; Dec., 1890.

A résumé of the more important dipterological matters commented upon, corrected, etc., in the first nine years of the journal.

Ein Beitrag zur "Bibliotheca Entomologica." Wiener Entomologische Zeitung, x, 65-96; April, 1891.

A digest of the author's thirty years of published work in entomology, mainly in the Diptera.

Hypocharassus gladiator, eine neue Dolichopoden-Art aus Nordamerika. Vehr. Zool.-Bot. Ges. Wien, 1878, 617-632, 1 pl.

Ueber Tachiniden, deren drittes Fühlerglied gespalten ist. Wiener Entomologische Zeitung, xiv, 101-103, 1895.

Remarks on *Dichocera* WILL., and other genera.

Bemerkungen zu den Dipteren-Gattungen Pelecocera Meig. and Rhopalomera Wd. Wiener Entomologische Zeitung, xiv, 133-135, 1895.

Chamaesyrphus n. g.; *Willistoniella* for *Rhopalomyia* WILL.

Note.—Mik published an enormous number of small items on Diptera, among which were occasional remarks on North American genera and species. These will be found in their appropriate places in the body of the Catalogue, but need not be cited in detail here. The two articles first given above will guide to many of the earlier of these notes, comments, corrections, etc.

Six new species.

Two New North American Cecidomyiidae. Proceedings of the Entomological Society of Philadelphia, VI, 219, 220, 1866.

Cecidomyia gleditchiae and *salicifoliae*.

Description of a New Species of Culicidæ. Transactions of the American Entomological Society, II, 47, 48, 1868.

Aedes sapphirinus.

The North American Tipulidæ. Part I; brevipalpi, Cylindrotomina and Ptychopterina. Monographs of North American Diptera, No. IV, in Smithsonian Miscellaneous Collections, vol. VIII; Washington, Jan., 1869. Pp. xi and 345, with four plates and several wood-cuts.

Many new species. Additions and corrections to this volume will be found at the end of Monograph III, published after No. IV.

Biological Notes on Diptera. Article First. Galls on Solidago. Transactions of the American Entomological Society, II, 299-303, 1869.

Asphondylia monacha and *Cecidomyia anthophila*.

Biological Notes on Diptera. Article Second. (1) A New American Asphondylia. (2) On some Undescribed Galls of Cecidomyia. Transactions of the American Entomological Society, III, 51-54, 1870-71.

Asphondylia rudbeckiae-conspicua; four new galls described and named.

Biological Notes on Diptera. Article Third. Transactions of the American Entomological Society, III, 345-347, 1870-71.

Diplosis resinicola; notes on several species.

A List of the Leptidæ, Mydaidæ and Dasypogonina of North America. Bulletin of the Buffalo Society of Natural Science, 1874, 169-187.

Mydas audax, *carbonifer* and *chrysostomus* n. sp.; the descriptions are reproduced in the Catalogue, 1878. Additions and corrections are given in the Bulletin, Nov., 1875, p. 71.

Prodrome of a Monograph of North American Tabanidæ. Memoirs of the Boston Society of Natural History, II, 365-397, 421-470, and 555-566, published in 1875-78.

Many new species.

Report on the Diptera Collected by Lieut. W. L. Carpenter in Colorado in the summer of 1873. Hayden's U. S. Geological and Geographical Survey of Colorado, 1873, 561-566. Washington, 1874.

Bibiocephala grandis n. g. and sp.

Three New Galls of Cecidomyiæ. Canadian Entomologist, Nov., 1875.
Cecidomyia verrucicola, urnicola; Asphondylia recondita.

Note on Some Diptera from the Island Guadelupe, Pacific Ocean, Collected by Mr. Palmer. Proceedings of the Boston Society of Natural History, xviii, 133, 134; Oct., 1875.

No new species; *Musca domestica* is the only one specifically determined.

Note.—There is also an island *Guadalupe*, in the West Indies, and a number of species of Diptera are reported from it.

On the North American Species of the Genus *Syrphus* (in the narrowest sense). Proceedings of the Boston Society of Natural History, xviii, 135-153; Oct., 1875.

Syrphus torvus, rectus, amalopis, contumax.

A List of North American Syrphide. Bulletin of the Buffalo Society of Natural Science, November, 1875, 38-71.

Nine new species described in the appendix. Additions and corrections are given in the Bulletin, May, 1876, p. 130. All the descriptions and notes are reproduced in the Catalogue, 1878.

Report on the Collection of Diptera made in portions of Colorado and Arizona during the year 1873. In Lieut. Geo. M. Wheeler's Report on the Explorations and Surveys West of the One Hundredth Meridian, vol. v, Zoology, 804-807. Washington; 1875.

Lasia klctti n. sp.

Blepharoptera defessa n. sp. In an article on "A New Cave-Fauna in Utah," by A. S. Packard. Bulletin of the U. S. Geological and Geographical Survey of the Territories, iii, No. 1, p. 168; 1877.

Report on the Diptera Collected by Dr. E. Bessels during the Arctic expedition of the Polaris in 1872. Proceedings of the Boston Society of Natural History, Dec., 1876.

Tipula besselsi n. sp.

Western Diptera. Descriptions of New Genera and Species of Diptera from the Region West of the Mississippi, and especially from California. Bulletin of the U. S. Geological and Geographical Survey of the Territories, iii, No. 2; April, 1877; pp. 189-354.

One hundred and thirty-six new species and several new genera.

Catalogue of the Described Diptera of North America (second edition). Smithsonian Miscellaneous Collections. Pp. xlvi and 276. Washington, 1878.

Two new genera and five new species are described in the notes, and a number of species redescribed. The work contains much more than an ordinary catalogue of so many species. It is in fact a mine of information on the order and its classification.

Bemerkungen über Blepharoceriden; ein Nachtrag zur "Revision" dieser Familie von Professor Dr. Loew. Deutsche Ent. Zeitsch., xxii, 405-416, 1878.

A review of the structural characters of the family; no new species.

An Essay of Comparative Chetotaxy, or the Arrangement of Characteristic Bristles of Diptera. Originally printed in Mittheil. d. Münchener Entomol. Vereins, v, 121-138, 1881; revised and republished in Trans. Entom. Society of London, 1884, pt. iv, pp. 497-517.

An attempt to locate and name the principal characteristic bristles (macrochaetae) of Diptera, as a means of classification; very important. No new species.

On Professor Brauer's Paper, "Versuch einer Characteristik der Gattungen der Notacanthen." Berl. Entom. Zeitsch., xxvi, 363-380, 1882.

Many notes on genera; no new species.

On the Genus Apioecera. Berl. Entom. Zeitsch., xxvii, 287-294, 1883; correction, xxx, 139, 1886; Second Notice on Apioecera, xxxvi, 311-316, 1891.
No new species.

Synonymica Concerning Exotic Dipterology. II. Berl. Entom. Zeitsch., xxvii, 295-298, 1883.

Dialysis WALKER, and other genera mentioned.

A Singular North American Fly. Berl. Entom. Zeitsch., xxvii, 299-300, 1883.

Opsebius pterodontinus n. sp.

Studies on Tipulidae. Part I. Review of the Published Genera of the Tipulidae longipalpi. Berl. Entom. Zeitsch., xxx, 153-188, 1886.

Brachyfrenna n. gen., from Texas.

Studies on Tipulidae. Part II. Review of the Published Genera of the Tipulidae brevipalpi. Berl. Entom. Zeitsch., xxxi, 163-242, 1887.

Rhamphidia albifarsis n. sp., from Porto Rico.

Biologia Centrali-Americanana. Vol. I. Cecidomyidæ-Empidæ. 216 pp., 3 col. plates. 128 pp. in 1886, the remainder in 1887.

Many new species, and a few genera.

On Mr. Portschinsky's publications on the larvae of Muscide, including a detailed abstract of his last paper, "Comparative biology of the necrophagous and coprophagous larvae." Berl. Entom. Zeitsch., xxxi, 17-28, 1887.

Although Portschinsky's work does not come within our faunal limits, relating to southern Russia, the subject is very interesting, and I cannot refrain from mentioning the paper. It forms a useful complement to Howard's paper on Diptera of excrement.

Some North American Tachinæ. Canadian Entomologist, xix, 161-166; Sept., 1887.

Five new species.

Chloropisca prolifica n. sp. Lintner's 4th New York Report, 60, 61, 1888.

See *Chlorops variceps*.

Suggestions Toward a Better Grouping of Certain Families of the Order Diptera. Entomologist's Monthly Mag., second series, II, 35-39, 1891.

Synopsis of the Described Genera and Species of the Blepharoceride. Berl. Entom. Zeitsch., xxxvi, 407-411, 1891.

Analytical tables of the genera and species, with references; no new species.

On the Characters of the Three Divisions of Diptera: Nemocera vera, Nemocera anomala, and Eremochaeta. Berl. Entom. Zeitsch., xxxvii, 417-466, 1892.

Explanatory Notice of my Views on the Sub-orders of Diptera. Entomologist's Monthly Magazine, second series, IV, 149, 150, 1893.

On the So-called Bugonia of the Ancients, and Its Relation to *Eristalis tenax*. Bull. Soc. Ent. Italiani, xxv, 186-217; 1893.

On the Oxen-born Bees of the Ancients (Bugonia), and their Relation to *Eristalis tenax*. Heidelberg, J. Hoerning, 1894, pp. xiv and 80.

This is a reprint and enlargement of the preceding. There is an additional article, pub. by J. Hoerning, 1895, 23 pp.

On the Atavie Index-Characters. Berl. Entom. Zeitsch., XXXIX, 69-76, 1894.

Western Pedicæ, Bittacomorphæ and Trichoceræ. Psyche, VII, 229-231; April, 1895.

Notes on several species from the Western States; none new.

Eristalis tenax in Chinese and Japanese Literature. Berl. Ent. Zeitsch., XL, 142-147, 1895.

Contributions to the Study of the Liponeuridae. Berl. Ent. Zeitsch., XL, 148-169, 1895.

Blepharoceridae; a study of generic characters, etc. A supplement to this paper is published in vol. XL, 351-355, 1895.

Preliminary Notice of a Subdivision of the Suborder Orthorhapha Brachycera on Chaetotactic Principles. Berl. Entom. Zeitsch., XLI, 365-373, 1896.

I have adopted for my catalogue almost the arrangement of this paper.

Identification of Two Genera of Nemestrinidæ published by Bigot. Berl. Entom. Zeitsch., XLII, 145-149, 1897.

Dicrotrypana BIG., and *Parasymmictus* BIG.

Amalopis Haliday (O. S.) versus *Tricyphona Bergroth* (not Zett.). Berl. Entom. Zeitsch., XLII, 150-154; 1897.

On the Synonymy of *Anopheles maculipennis* Meigen. Entomol. Monthly Mag., sec. ser., XI, 281, 282; Dec., 1900.

Maculipennis vindicated as against *claviger* FAB.

On the New Nomenclature of the Cecidomyidæ. Entomol. Monthly Mag., sec. ser., XII, 40-43, 1901.

Opposing the abandonment of the old genus *Cecidomyia*, as finally developed by Meigen and Latreille. For reasons explained at the beginning of the family, I have adopted the "new nomenclature."

The Position of Phora in the System of Diptera. Entomol. Monthly Mag., XIII, 204, 205, 1902.

On a Distinctive Character of the Imagos of the Suborders of Diptera. Ent. Monthly Mag., XIII, 228, 1902.

Record of My Life Work in Entomology. Parts I and II. Cambridge, Mass.; Oct., 1903, 204 pp. Part III, Heidelberg, 1904, pp. 205-240, with portrait.

Baron Osten Sacken's autobiographical volume contains so much information about the earlier work on North American Diptera, and the development of dipterological science in general, that every student of the order will find it extremely interesting and valuable. His rare and noble devotion to science throughout a long career should be an inspiring example.

Packard, Alpheus S.

On Insects Inhabiting Salt Water. Proceedings of the Essex Institute, VI, 41; March, 1860.

Ephydria halophila and *Chironomus helophilus* n. spp.

On Insects Inhabiting Salt Water. No. 2. American Journal of Science and Arts, 3d series, 1, 100, 1872.

Ephydra gracilis and *californica*, described from larvae; adults unknown. Report upon the Invertebrate Animals of Vineyard Sound, etc. Washington, 1874.

Several larvae of Diptera; *Chironomus halophilus* n. sp.

On the Transformations of the common House-fly. Boston Society of Natural History, xvi, 130-150, 1 plate; 1874.

Insects affecting the Cranberry, with Remarks on other Injurious Insects. Report U. S. Geol. Survey for 1876 (pub. 1878), 527.

Diplosis pini-rigidae n. sp., on *Pinus rigida*.

The Hessian Fly. Bull. No. 4, U. S. Entomological Commission, 1880, 43 pp., figs.

Bot-Fly Larvae in a Turtle's Neck. American Naturalist, xvi, 508, fig.; July, 1882. Not determined; perhaps not an Oestrid.

Larvae of a Fly in a Hot Spring in Colorado. American Naturalist, xvi, 599, 600; July, 1882.

Stratiomyia sp.; larvae in water at 157 degrees Fahrenheit.

The Hessian Fly. In the Third Report of the U. S. Entomological Commission, 1883, 198-248, figs., etc.

Forest Insects. Being the Fifth Report of the United State Entomological Commission. Washington, 1890, 955 pp., with many plates and figures.

No new species of Diptera; life history of many species briefly given.

The Entomological Writings of Alpheus S. Packard. A bibliography by Samuel Henshaw. Division of Entomology, 1887, 49 pp.

Palisot de Beauvois, A. M. F. J.

Insectes recueillis en Afrique et en Amérique, etc. Paris, 1805-21; with plates.

Several Tabani, one Chrysops, and one Syrphid are described and figured.

Pergande, Theodore.

The Ant-Decapitating Fly. Proceedings of the Entomological Society of Washington, iv, 408; July 2, 1901.

Life history of the species; described by Coquillett in same article as *Apoccephalus pergandi* n. gen. et sp.

Pettit, Rufus H.

Bulletin 175, Michigan Exper. Station; July, 1890; pp. 350-361, notes on Hessian Fly and on the Beet-Leaf Miner, *Pegomyia vicina*.

Bulletin 186, Michigan Exper. Station, and also Annual Report of same for 1901, contains a list of Diptera collected in Northern Michigan, and an article with good figure on the Potato-Beetle Tachinid, *Phorocera doryphora*.

A Leaf-mining Chironomus sp. in Water-lilies. Mich. Acad. Science, 1900, p. 110, with plate. Habits of an undetermined species. Compare *Cricotopus sylvestris*.

Perty, Maximilian.

Delectus Animalium articulatorum quae in Itinere per Brasiliam Annis 1817-1820, etc., collegerunt Dr. Spix et Dr. Martius. Monachii, 1830-34, 4to, with 40 plates.

Several species described here occur also in Cuba and Mexico.

Poey, Felipe.

Memorias sobre la Historia Natural de la Isla de Cuba. Tomo I. Habana, 1851-54.

Occacta furens n. gen. et sp.

Reiche, L.

Description du cinque espèces nouvelles d'Insectes, provenant de l'Expédition aux Mers arctiques. Annales Soc. Ent. France, Bulletin, p. ix, 1857.

Anthomyia impudica (is a *Cordylura*—O. S.).

Riley, Charles V.

First Report of the State Entomologist of Missouri. Jefferson City, 1869.

Life history and description of *Anthomyia zeas* n. sp. (syn. of *Phorbia fusciceps*), *Lydella doryphoræ* n. sp. (see *Phorocera*), *Pipiza radicum* n. sp. (probably syn. of *P. femoralis*); also *Meromyza americana*, *Oestrus ovis*, and *Trupanea apivora* FITCH (*Promachus fitchii* WILL.).

The Cecropia Moth. American Entomologist, II, 97-102; Feb., 1870.

Exorista cecropiae n. sp. (syn. of *Winthemia quadripustulata*).

Second Missouri Report, 1870.

Life history and description of *Asilus missouriensis* n. sp (*Proctacanthus milberti*), *Exorista flavicauda* n. sp. (*Belvosia unifasciata*), and of *Tabanus atratus*.

Fourth Missouri Report, 1872.

Tachina anonyma n. sp. (*Frontina frenchii*), and *T. phycitæ* LEBARON (*Exorista pystæ*).

Fifth Missouri Report, 1873.

Descriptions of several galls of Cecidomyiidae on grape.

Descriptions and Natural History of two Insects which brave the Dangers of *Sarracenia variolaris*. Trans. Acad. Nat. Sci. St. Louis, III, 235-240; 1875.

Sarcophaga sarracenia n. sp.

The Clover-Seed Midge. Report of the Commissioner of Agriculture for 1878 (pub. Oct., 1879), 248-250.

Cecidomyia leguminicola LINTNER, life history.

Parasites of the Cotton Worm. Canad. Entomol., XI, 161-162, 1879.

Tachina alcticæ n. sp. (see *Frontina alcticæ*).

Natural Enemies of the Locust. Second Report of the U. S. Entomological Commission, 1880 (pub. 1881), 259-270.

Life history of *Systochus orcas* and *Triodites mus*, reared from locust eggs; some other Diptera mentioned.

Dipterous Enemies of Phylloxera vastatrix. Canadian Entomologist, XV, 39; Feb., 1883.

Mentions *Leucopis phylloxerae* MS., which was never described.

Occurrence of a Stratiomyia larvæ in Sea-water. American Naturalist, XVII, 1287; Dec., 1883.

Not determined.

Report of the Entomologist. In the Report of the Commissioner of Agriculture for 1884 (pub. Jan. 31, 1885).

Contains articles on *Oscinis brassicæ* n. sp. (*Agromyza trifolii*), *Anthomyia* (*Phorbia*) *brassicæ*, and *Simulium* sp.

Natural Enemies of the Cotton-Worm. Fourth Report U. S. Entom. Com., 87-119; Feb. 3, 1886.

Phora alcticæ n. sp. (*nigriceps*).

Zwei neue nordamerikanische Dipteren. Wiener Entomol. Zeitung, IX, 230; Oct., 1890.

Bittacomorpha sackenii and *Agathon elegantulus*, from Nevada; the latter a new genus, regarded by Kellogg as a synonym of *Bibiocephala*.

Ueber die Dipteren-Gattung *Stylogaster* Macq. Wiener Entomol. Zeitung, XI, 286; Nov., 1892.

Ueber *Trypetia amabilis* Loew. Wiener Entomol. Zeitung, XIII, 97; March, 1894.

Redesc. and figured; see *Hemiracheta amabilis*.

Ueber *Mydas fulvipes* Walsh. Wiener Entomol. Zeitung, XIII, 169, 170, 1894.

Rondani, Camillo.

Diptera exotica, revisa et notata, novis nonnullis descriptis. Archivio Canestrini, III, 1863.

Scatina estotilandica n. sp. from Labrador.

Osservazioni sopra alquante specie di esopodi ditteri del Museo Tormense. Nuovi Annali di Bologna, ser. 3, II, 165-197, 1850.

Tabanus cheliopterus n. sp., from Carolina.

Hippoboscita exotica non vel minus cognita. Annali del Museo Civico di Storia Naturale di Genova, XII, 150-169, 1878.

Six new species of Hippoboscidae from Mexico.

Ruebsaamen, Ewald H.

Sciara striata n. sp. Berliner Entomol. Zeitschr., 1894, 37.

From Mexico.

Zoolog. Ergebnisse der . . . Grönland expedition. Grönlandische Mycetophiliden, Sciariiden, Cecidomyiden, Psylliden, etc. In Bibliotheca Zoologica, XX, 103-119, 2 plates; 1898.

Six new species of *Sciara* from Greenland.

Saint Fargeau et Serville.

Encyclopédie Méthodique, vol. x. Paris, 1825.

A number of North American Diptera are mentioned; none new.

Say, Thomas.

Diopsis brevicornis n. sp. Journal of the Academy of Natural Sciences of Philadelphia, I, 23, 1817.

Some Account of the Insect known as the Hessian Fly, etc. Jour. Acad. Nat. Sci. Phil., I, 45-48 and 63-64; 1817. *Cecidomyia destructor* first described.

Description of Dipterous Insects of the United States. Journal of the Academy of Natural Sciences in Philadelphia, III, 9-54 and 73-104; 1823.

Description of North American Dipterous Insects. Journal Academy of Natural Sciences in Philadelphia, VI, 149-178 and 183-188; 1829-30.

Keating's Narrative of an Expedition to the Source of St. Peter's River, etc., under the Command of S. H. Long. 2 vols.; Philadelphia, 1824. Insects described by Say in the Appendix to the second volume, Diptera, pp. 357-378. Cited as "Long's Exped."

Description of new species of North American Insects found in Louisiana by Jos. Barabino. New Harmony, Ind., March, 1831 (not in the Complete Works; see Scudder, in Psyche, Jan., 1890, where the description of the single new species is quoted).

New Species of North American Insects found by Jos. Barabino in Louisiana, New Harmony, Ind., 1832.

American Entomology. 3 vols., with plates. Philadelphia, 1824-25-28.

The Complete Writings of Thomas Say on the Entomology of North America, with a Memoir of the Author by George Ord. Edited by John L. Leconte. New York, 1859; 2 vols., 8 vo; 1200 pp., with 30 plates.

There is also a French translation of Say's works, in vol. v of Annales Soc. Ent. de France, 1837.

There are about 250 new species of North American Diptera in Say's writings.

Say sent many of his species of Diptera to Wiedemann, who redescribed them in his Aussereropäische Zweifl. Ins. In many cases the latter description is more characteristic than Say's.

Shimer, Henry.

Description of a New Species of *Cecidomyia*. Transactions of the American Entomological Society, I, 281, 1868.

Cecidomyia acris, n. sp.

A Summer's Study of Hickory-galls, with Descriptions of Supposed New Insects Bred from them. Transactions of the American Entomological Society, II, 380, 1869.

Cecidomyia cossae, n. sp.

Additional Notes on the Striped Squash-Beetle (*Diabrotica vittata*). American Naturalist, V, 217, 1871.

Melanosphora diabrotice, n. sp., here placed in *Celatoria*.

Schiner, J. R.

Fauna Austriaca. Diptera. Vienna, 2 vols., 1862-64.

Incomparably the best encyclopaedic work on Diptera that was ever published. While it is intended to include only Austrian forms, many of the species occur in North America, and most of the genera.

Neue oder wenig bekannte Asiliden des kaiserl. Hofcabinets in Wien. Verhandlungen der zoologischen-botanischen Gesellschaft zu Wien, XVII, 355-412, 1867.

Five new N. A. species.

Reise der Oesterr. Fregatte Novara um die Erde in den Jahren 1857-59. Zoologischer Theil. Diptera. Wien, 1868, 1 vol. 4to, with 4 plates.

Many South American species which also occur in North America are described; also some new genera occurring in North America.

Schnabl, Johann.

Limnospila nov. gen. *Anthomyidarum*. Wiener Ent. Zeitung, XXI, III, 1902.

Type, *Canosia albifrons*, which occurs in North America.

Schwarz, E. A.

The Insect Fauna of the Great Salt Lake, Utah. Canadian Entomologist, XXIII, 235-241, 1891.

Extended notes on the larva of *Ephydria gracilis* Pack.

The Hippelates Plague in Florida. Insect Life, vii, 374-379, figs.; July, 1895.
Notes on *H. flavipes* and *plcbeius*, annoying people in Florida.

Scudder, Samuel H.

Description of Tachina theclarum, in an article by Osten Sacken, Canadian Entomologist, xix, 166; Sept., 1887.

The species is referred by Coquillett to *Exorista confinis* FALL.

An Unknown Tract on American Insects by Thomas Say. Psyche, Jan., 1899, 306-308.

Contains reprint of *Trypetia trifasciata* SAY.

Note.—Mr. Scudder's work on fossil Diptera is not listed, not being within the scope of the present catalogue.

Schiödte, J. G.

Naturhistoriske Tilläg til Rink: "Grönland geographisk og statistisk beskrevet," 1857; a German translation of the "Tilläg" or appendix was printed in Berliner Entomolog. Zeitschr., 1859, 134-157.

No new species; some synonymy, and a list of described Diptera from Greenland.

Sirrine, F. A.

The Spinach-leaf Maggot or Miner. Bull. 99, N. Y. Experiment Station; Jan., 1896; pp. 21-31, figs. Also in Annual Report N. Y. Exp. Sta. for 1895 (pub. 1896), 625-633, 1 plate.

Life history of *Pegomyia vicina* LINT.

A Little-known Asparagus Pest (*Agromyza simplex* Lw.). Bull. 189, N. Y. Exp. Sta.; 1900.

Skinner, Henry.

Diptera of Beulah, New Mexico. Trans. Amer. Entom. Society, xxix, 104-106; Feb., 1903.

About 135 species listed. The new ones described by Coquillett and Johnson, *q. v.*

Slingerland, Mark Vernon.

The Cabbage Root Maggot, with Notes on the Onion Maggot and Allied Insects. Bull. 78, Cornell University Exp. Station; Nov., 1894, pp. 481-577, 18 figs.

Life history of *Phorbia brassica* BOUCNÉ, and notes on other species. An admirably thorough piece of work.

The Current-Stem Girdler and the Raspberry-Cane Maggot. Bull. 126, Cornell University Exp. Sta.; Feb., 1897, pp. 39-60, figs.

The Raspberry-Cane Maggot is described and its habits given, with bibliography, but the species is not determined. It is mentioned as *Phorbia* sp. See next article.

The Raspberry-Cane Maggot. Canadian Entomologist, xxix, 162, 163; July, 1897.

Life history; described in the article as *Phorbia rubivora* by Coquillett.

A New Cherry Pest. Bull. 172, Cornell University Exp. Sta., Sept., 1899; 19 pp., 15 figs.

Supposed to be *Rhagoletis cingulata* LOEW; the determination is confirmed from bred specimens in Canad. Ent., xxxiv, 28, 1902.

Slosson, Annie Trumbull.

List of Diptera from the White Mountains, New Hampshire. In Entomological News, as follows: Vol. v, 6; vi, 6, 7 and 319, 320; vii, 263, 264; viii, 239, 240; ix, 252; xi, 320, 321; xiii, 7, 8 and 319, 320.

In all several hundred species, none described as new, but some European species and genera not hitherto reported from the United States. The determinations are almost all by Coquillett.

Mount Washington Again. Entomological News, v, 271-274, 1894.

Collecting notes; several Diptera mentioned.

Singular habit of a Cecidomyiid. Entomological News, vii, 238, 1896.

An undetermined species riding on the wing of a flying Chrysopa.

Hunting Empids. Entomological News, xiv, 265-268, 1903.

Collecting notes; habits of several species.

Smith, John B.

Note on Habits of *Volucella fasciata*. Canadian Entomologist, xxiii, 242, 243, 1891.

The Horn Fly. Special Bulletin No. 62, New Jersey Experiment Station, Nov., 1889; 40 pp., 9 figs.

Life history of *Hæmatobia serrata* DESV.

The Insects Injurious affecting Cranberries. Special Bulletin K, N. J. Exp. Sta., Feb., 1890; 43 pp., 26 figs.

Cecidomyia vaccinii, n. sp.; the name was changed by Johnson to *oxy-coccana*, on account of preoccupation.

A Contribution towards the Knowledge of the Mouth Parts of Diptera. Trans. Amer. Entom. Society, xxii, 319-339, 1890.

Notes on the Structure and History of *Hæmatobia serrata* Desv. Psyche, v, 343-347, figs., 1890.

An Essay on the Development of the Mouth Parts of Certain Insects. Transactions of the American Philosophical Society, xix, 175-198, 3 plates; 1896.

Treats of mouth ports of Diptera especially.

Life History of *Aedes smithii*. Jour. N. Y. Ent. Society, x, 10-15; Mar. 1902.

Notes on the early Stages of *Corethra brakeleyi*. Canadian Entomologist, xxxiv, 139; June, 1902.

The Salt-Marsh Mosquito. Special Bulletin T, N. J. Exp. Sta., 1902; 10 pp., figs.

Life history of *Culex sollicitans* WALK.

Notes on the Early Stages of *Culex canadensis* Theob. Entomological News, xiii, 267-273; Nov., 1902.

Characters of some Mosquito Larvæ. Entomological News, xiii, 299-303, 1 pl.; Dec., 1902.

Report of the Entomological Department of the N. J. Exp. Sta. for 1902.

A Report on Mosquito Investigations, pp. 511-556, mostly on the Salt-Marsh Mosquito, *Culex sollicitans* Walk. Also has an article on Mosquitoes and malaria, by Herbert Parlin Johnson.

Notes on *Culex serratus* Theob. Entomological News, xiv, 309-311, 1 pl.; Dec., 1903.

Snodgrass, R. E.

The Inverted Hypopygium of *Dasyllis* and *Laphria*. Psyche, x, 399, 400, 1902.

Purely morphological.

The Terminal Abdominal Segments of Female Tipulidæ. Jour. N. Y. Ent. Soc., xi, 177-188, 2 pl.; December, 1903.

Characters of several previously-known species described.

Snow, F. H.

Musca domestica L. versus *Vespa occidentalis* Cress. *Psyche*, III, 340; May, 1882.

Notes on the distribution of *Musca domestica*.

A Preliminary List of the Diptera of Kansas. *Kans. Univ. Sci. Bull.*, II, 211-223; Nov., 1903.

392 species listed; 6 new species are described by Adams. Unfortunately this reached me so late that I could add only the new species to the catalogue.

Snow, William A.

The Moose-fly—A New Haematobia. *Canadian Entomologist*, xxiii, 87-89, 1891.

Haematobia alcis, n. sp., from Northern Minnesota.

Notes and Descriptions of Syrphidae. *Kans. Univ. Quarterly*, I, 33-40, 1 pl., 1892.

Four new species; many others mentioned.

Descriptions of North American Trypetidae. *Kans. Univ. Quarterly*, II, 159-174, 2 plates, 1894.

Fourteen new species; *Xenochacta* and *Polymorphomyia* n. gen.

American Platypezidae. *Kans. Univ. Quart.*, III, 143-152, 1 pl., 1894.

American Platypezidae. II. *Op cit.*, III, 205-207; 1895.

In these papers eleven new species are described; there are also tables of genera and species.

Cnephalia and its Allies. *Kans. Univ. Quarterly*, III, 177-186, 1895.

A study of the genera in the neighborhood of Gonia and Spallanzinia; *Cnephalia pansa* and *finitima*, n. sp.

A New Species of Pelecocera. *Kans. Univ. Quarterly*, III, 187, 1895.

P. willistoni, from New Mexico.

Diptera of Colorado and New Mexico. *Kans. Univ. Quarterly*, III, 225-247, 1895.

Confined to Syrphidae. 13 n. spp.; notes on many other western species.

Supplementary List of North American Syrphidae. *Kans. Univ. Quarterly*, III, 249-262, 1895.

List of species from 1878, with some changes in nomenclature.

On Toxotrypana of Gerstaeker. *Kans. Univ. Quart.*, IV, 117-119, fig., 1895.

A List of Asilidae, Supplementary to Osten Sacken's Catalogue, etc. *Kans. Univ. Quarterly*, IV, 173-190, 1896.

Considerable changes in synonymy, especially of the tropical species.

Snow, W. A. and Mills, Helen.

The Destructive Diplosis of the Monterey Pine. *Entomological News*, XI, 490-494, 1 plate; June, 1900.

Diplosis pini-radiata n. sp.

Snyder, Mrs. A. J.

Trypetia solidaginis. *Canadian Entomologist*, XXX, 99, 100; Apr., 1898.

Description of the emergence of the adult.

Speiser, Paul.

Über die Nycteriibiden. *Wiegmann's Archiv. für Naturgeschichte*, LXVII, 11-78, 1 plate; 1901.

Important for the classification; no new North American species.

Besprechung einiger Gattungen und Arten der Diptera pupipara. Termesz. Füzetek, xxv, 1902, 327-338.

Ornithomyia erythrocephala LEACH is made the type of a new genus, *Ornithoctona*; *Ornithoeca confluenta* SAY redesc.

Studien über Diptera Pupipara. Zeitschr. f. Syst. Hym. und Dipterologie, III, 145-180, 1903.

A very thorough work, referring to several North American species; *Lynchia pusilla* n. sp., from Cuba. Bigot's types in the family are elucidated, from examination.

Staeger, C.

Groenland's Antiater. In Kröyer's Naturhist. Tidskrift, new ser., I, 346-360, 1845.

Eight new species; fifty-five species mentioned in all.

Stedman, J. M.

Thirty-fourth Report Board of Agriculture of Missouri, 1902.

Contains articles on Hessian Fly (p. 76) and Wheat Bulb-Worm (p. 85); no new species.

Stein, P.

Die Anthomyiden-Gruppe Homalomyia. Berliner Entom. Zeitsch., XL, 1-146, 1895.

Several North American species also occurring in Europe are redesc.

Nordamerikanischen Anthomyiden. Berliner Entom. Zeitsch., XLII, 161-288, 1897.

Many new species, several new genera; the foundation of our knowledge of the North American fauna in this family.

Die Walker'schen Aussereuropäischen Anthomyiden in der Sammlung des British Museums zu London. Zeitschr. f. Syst. Hym. und Dipterologie, 1901, 185-221.

A reexamination of Walker's types, with descriptions of many. Three labeled but unpublished species of Walker are described—*Hydrotia succedens*, *Hylemyia relata* and *Pegomyia debilis*, from North America. These of course are credited to Stein, not Walker.

Die Zetterstedt'schen, Holmgren'schen und Boheman'schen Anthomyidentypen des Stockholmer Museums. Wiener Entom. Zeitung, XXI, 29-66, 1902.

Holmgren's Greenland species are elucidated.

Summa, H.

The Pseudo-parasitism of Diptera in Man, or Myiasis. St. Louis Med. & Surg. Journal; April, May and June, 1889; sep., 16 pp., 5 figs.

Swederus, Samuel.

Et Nytt Genus och Femto Nya Species af Inseeter. In the Vetenskap. Acad. Nya Handl., 1787, p. 181 and 276.

"Two North American species: *Musca tomentosa*, which is probably *Brachypalpus verbosus*, and *Musca (Syphus) monoculus*; I cannot make out the synonymy of the latter."—O. S.

Theobald, Fred. V.

A Monograph of the Culicidae of the World. London, British Museum. Vols. I and II and vol. of col. plates, 1901; Vol. III, 1903.

All the North American species known at the time of preparation are redescribed in this great work; there are also numerous new species, espe-

cially from along the southern limits of our field. In the 3d volume many new genera are introduced. The classification of Theobald is closely followed herein.

Description of a New N. A. Culex. Canadian Entomologist, xxxv, 211-213, 1903.

C. Kelloggii, which is a synonym of *C. tarsalis* COQ.

Notes on Culicidae and their Larvae from Pecos, N. M., and Description of a New Grabhamia. Canadian Entomologist, xxxv, 311-316, 1903.

G. vittata.

Thomson, C. G.

Kongliga Svenska Fregatten Eugenies Resa Omkring Jorden. Diptera. Stockholm, 1868; 1 vol., 4to.

Forty-nine new species from California and Panama.

Thunberg, Carl P.

Description of Pantophthalmus tabaninus, in Acta Soc. Gotheburg, 1819, pars. III, 7, pl. vii, f. 2. So quoted by Wiedemann, who reproduces the description in Auss. Zweifl., I, 110. The paper is not mentioned by Hagen in his Bibliotheca.

Townsend, C. H. Tyler.

Breeding records of 27 species, reared by Professor S. A. Forbes; *Sarcophaga leucania* n. sp. "if found to be undescribed."

Comments on Mr. Van der Wulp's Recent Diagnoses of New Species of Mexican Muscidae. Canadian Entomologist, xxv, 164-168; July, 1893.

An attempt to interpret Van der Wulp's too brief diagnoses, without the material to throw any particular light on them; an altogether superfluous piece of meddling. The changes of generic names are both uncalled for.

A Cabbage-like Cecidomyiidous Gall on Bigelovia. Psyche, vi, 490; July, 1893.

Cecidomyia bigeloviae-brassicoides n. sp.; gall only.

Further Notes on the Cotton-tail Bot. Insect Life, v, 317-320; July, 1893.

Cuterebra fontinella CLARK redescribed. This afterward proved to be a new species and was named *C. lepusculi* in Psyche, Jan., 1897, 8, 9.

Notes on Some Jamaican Muscidae. Journal of the Institute of Jamaica, i, No. 7; Aug., 1893.

No new species.

Dipterous Parasites in Their Relation to Economic Entomology. Insect Life, vi, 201-204; Dec., 1893.

No new species.

Notes on some Cecidomyiidae of the Vicinity of Washington, D. C. Proc. Ent. Soc. Wash., ii, No. 4, pp. 388-390; 1893.

Three species mentioned; none new.

Notes on Certain Cecidomyiidous Galls on Cornus. Proc. Ent. Soc. Wash., ii, 390, 1893.

Describes the gall of the species afterward named *Cecidomyia clavula* by Beutennüller.

Occurrence of Oecacta furens Poey in Jamaica. Jour. Inst. Jamaica, i, 381, 1893.

A Tachinid Reared from the Cells of a Mud-dauber Wasp. Bulletin Ohio Exp. Station, Technical series i, 165, 166; 1893.

Sarcomacronychia trypoxylonis n. sp., from Ohio (syn. of *Pachyophaethalus floridensis* TOWNS.).

A very Remarkable and Anomalous Syrphid, with Peculiarly Developed Hind Tarsi. Canadian Entomologist, xxvi, 50-52, figs.; Feb., 1894.

Calotarsa ornatipes n. gen. and spec. It belongs to the Platypezidae, and the genus is but little different from *Platypeza*. Townsend published another note on same, p. 102.

New Santo Domingo Tachinidae. Jour. New York Entomological Society, ii, 78, 79; June, 1894.

Trichopoda subciliata n. sp. and *Ocypterosipho willistoni* n. gen. and species; the latter is a syn. of *Beskia clops*, according to Coquillett.

A Cone-like Cecidomyid Gall on Bigelovia. Psyche, vii, 176; Dec., 1894.

Cecidomyia bigeloviae-strobiloides n. sp.; gall only.

On the Horse-Flies of New Mexico and Arizona. Kansas Academy of Science, 1894, 133-135.

Diachlorus guttatus n. sp., afterward referred to *Tabanus*.

Note on a Peculiar Acalyptrate Muscid found near Turkey Tanks, Ariz. Kansas Acad. of Science, 1894, 135, 136.

Micropeza turcana n. sp.

Contributions to the Dipterology of North America.

I. Syrphidae. Trans. Amer. Ent. Soc., xxii, 33-55; March, 1895.

Mentions 75 species of Syrphidae, 8 new.

II. Tabanidae, Conopidae, Tachinidae, etc. Ibid., 55-80.

Notes on many species of these families, 9 new.

Notes on The Diptera of Baja California. Proc. Cal. Acad. Acad. Sci., ser. 2, vol. iv, 593-620; Apr., 1895.

Occurrence and notes on many species; 14 new.

Note.—Baja California is Lower California, and is so cited in the catalogue. It is in Mexico.

On the Cabbage-shaped Gall of *Cecidomyia salicis-brassicoides*, and its Occupants. Canadian Entomologist, xxvii, 205-207; Aug., 1895.

On the Correlation of Habits in Nemocerous and Brachycerous Diptera between Aquatic Larvae and Blood-sucking Adult Females. Jour. N. Y. Ent. Soc., iii, 134-136; Sept., 1895.

No new species.

On the Bio-geography of Mexico, Texas, New Mexico and Arizona. Texas Acad. Science, Dec., 1895, pp. 77-96 and June, 1897, pp. 33-86.

The second part contains some local lists of Diptera; all or nearly all are printed in other papers.

Notes on the Species of *Exorista* of Temperate North America. Psyche, vii, 329-331; Jan., 1896.

E. nigripalpis n. sp.

On a Collection of Diptera from the Lowlands of Rio Nautla in the State of Vera Cruz. Annals and Mag. of Nat. Hist., ser. 6, vol. xix, 15-34, and xx, 20-33 and 272-291; January, July and September, 1897.

16 new species; a few varieties named; notes on a number of species.

Diptera from the Sacramento and White Mountains in Southern New Mexico. Annals and Mag. of Nat. Hist., ser. 6, vol. xix; Feb., 1897.

Pipiza occidentalis, *Milesia bella*, *Echinomyia victoria* and *neglecta*, new; the last two are assigned by Coquillett to *Archytas lateralis* and *Peleteria tessellata*.

Diptera from Yucatan and Campeche. I. Canadian Entomologist, xxix, 197-199; Aug., 1897.

Tabanus campechianus and *yucatanus* n. spp.; notes on others.

Diptera from the Lower Rio Grande or Tamaulipan Region of Texas. Journal of the New York Entomological Society, v, 171-190; Dec., 1897.

Simulium tamaulipense, *Baccha tropicalis*, *Zodion albonotatum* n. spp.; notes on others.

Part II of same, vi, 50-52; 1898; contains one new sp., *Volucella tamaulipana*, with notes on other species.

Description of the Bot-fly of the Cotton-tail Rabbit in New Mexico. Psyche, viii, 8, 9; Jan., 1897.

Cuterebra lepusculi n. sp.

Diptera from the Head Waters of the Gila River. I. Psyche, viii, 38-41; Mar., 1897.

Chrysops ceras and *facialis*, *Myobia gilensis* n. spp., and a few notes.

II. Ibid., pp. 92-94; July, 1897.

Tabanus gilannus and *intensivus* n. spp.; notes on three species.

Some characteristic maritime Diptera from the South End of Padre Island and the adjacent Texas Coast. I. Entomological News, ix, 167-169; Sept., 1898.

Tabanus maritimus and *Lipocheta texensis* (syn. of *slossonae*) n. spp.

Diptera from the Organ Mountains of Southern New Mexico.

I. Psyche, viii, 126-128; Oct., 1897.

Notes on four species, none new.

II. Psyche, viii, 267-269; Oct., 1898.

Notes on seven species; *Gædiopsis monticola*, new.

Diptera from the White Sands on the Tularosa Plains of Southern New Mexico. I. Psyche, viii, 138-140; Nov., 1897.

A few notes on variations of species, etc.; no new species.

Diptera from the Mesilla Valley of the Rio Grande in New Mexico.

I. Psyche, viii, 147-150; Dec., 1897.

Notes on a dozen species, none new.

II. Ibid., 211, 212; May, 1898.

Notes on three or four species, none new.

New and Little-known Diptera from the Organ Mountains and Vicinity in New Mexico. Transactions of the American Entomological Society, xxvii, 159-164; 1901.

Four new species; notes on a number of old ones.

A Bot-like Parasite of a Bird. Journal Institute of Jamaica.

Not seen; I am unable to complete the reference.

Van der Wulp, Frederick M.

Eenige noordamerikaansche Diptera. Tijdschrift voor Entomologie, x, 125-164, 3 pl.; 1867 (Also cited as vol. ii, sec. series; Osten uses this form, and I have followed him, but in later work Van der Wulp cites it as vol. x).

30 new N. A. spp., 18 European species recognized, and 24 described N. A. spp. identified, all from Wisconsin.

Nog iets over Noordamerikaansche Diptera. Tijdschrift v. Ent., xii (or iv, sec. ser.), 80-86; 1869.

Five new N. A. species.

Opmerkungen omtrent Uitlandische Asiliden. Tijdschrift v. Ent., xiii (or v, sec. ser.), sep. 11 pp., 1 pl.; 1870.

Stenopogon ochracoccus n. sp., from North America.

Amerikaansche Diptera.

No. 1. Tijdsch. v. Ent., xxix, 141-168, 1 col. plate; 1881.

No. 2. Tijdsch. v. Ent., xxv, 77-130, 2 col. plates; 1883.

No. 3. Tijdsch. v. Ent., xxvi, 1-60, 2 col. plates; 1883.

These contain 14 new species from North America, with notes on about 127 other species.

Notes from the Leyden Museum. iv, 73-93, 1882.

Anthrax melasoma and *Jurinia nitida* n. spp., the former redesc. in Amer. Dipt., No. 2.

Chrysops geminata Wied. and Macq. Wiener Ent. Zeitung, iii, 139-141, 1884.

Chrysops crassicornis n. sp., from Guanajuato, Mex.

Quelques Diptères Exotiques. Comptes Rendus de la Soc. Ent. Belgique, xxvii, p. cxcii, 1884.

Hystricia cyaniventris n. sp., from Guanajuato, Mex.

Nalezing over Amerikaansche Diptera. Tijdsch. v. Ent., xxvii, 1884; sep. 3 pp.

Notes on four described species from New England.

Langwerpige Dexinen-Formen. Tijdsch. v. Ent., xxviii, 189-200, 1 col. plate; 1885.

Euantha and *Leptoda* n. gen.; the species were previously described.

Sarcophagula, een nieuw Geslacht der Sarcophaginiæ. Tijdsch. v. Ent., xxx, 173, 174, 1887.

No new species.

Biologia Centrali-Americanica. Diptera, vol. II. Pp. 1-489, 13 col. plates, title-page, introduction, and index of plate-figures. London; April, 1888, to May, 1903. The date is printed at the bottom of every eighth page.

Many new genera and species.

Eenige Uitlandische Diptera. Tijdschr. v. Ent., xxxiv, 193-218, 1891.

Volucella testacea n. sp., from Curaçao.

Diagnoses of New Mexican Muscidae. Tijdsch. v. Ent., xxxv, 183-195, 1892.

Four genera and about 60 species new; all described in full in subsequent parts of Biologia.

Vanhoffen, E.

Fauna und Flora Grönlands. Grönländs-Expedition der Gesell. für Erdkunde zu Berlin, 1891-93, unter Leitung v. Erich v. Drygalski. Vol. II, I, 1897.

Contains a list of Greenland Diptera, compiled, pp. 156, 157. This is reproduced by Lundbeck, Dipt. Groenl., II, 314, correcting nomenclature.

Verrall, G. H.

British Flies. Vol. VIII: Platopezidæ, Pipunculidæ and Syrphidæ. London, Gurney and Jackson, 1901. With catalogue and bibliography in appendix. Pp. 691 and 121; many figures in the text.

This fine work contains descriptions of many genera and a considerable number of species, common to Great Britain and North America.

Walker, Francis.

List of the Specimens of Dipterous Insects in the Collection of the British Museum. Four parts and three supplements. London; 1848-55. The dates are as follows: Part I, 1848; II, III, and IV, 1849; Suppl. I, II, 1854; III, 1855.

Many new species.

Note.—In the Osten Sacken catalogue occur many species of Walker with the locality "Huds. B. Terr." These are cited by Walker as "St. Martin's Falls, Albany River, Hudson Bay." I requested Dr. Jas. Fletcher to find this locality for me on the modern maps; he found it now named Martin's Falls, and located in longitude 86.30, latitude 51.30,—in other words, about 200 miles north of the northern arch of Lake Superior.

Insecta Saundersiana. Diptera. Five Parts, with eight plates by Westwood. London, 1850-56. Dates as follows: Part I in 1850, II, in 1851, III and IV in 1852, and V in 1856.

Many species and a few genera.

Characters of Undescribed Diptera in the Collection of Wm. Saunders. Transactions of the Entomological Society [of London], new series, IV, 1857. pp. 119-158 and 190-235; V, 1858, 268-334.

Many new species, mostly described in a very brief and unsatisfactory manner.

On Some Insects of Nova Scotia and Canada. Canadian Entomologist, III, 141; Oct., 1871.

A short list of Diptera occurring in Nova Scotia; no new species.

In the appendix to "The Naturalist in Vancouver Island and British Columbia," by J. K. Lord (London, 1866, 2 vols.), Walker described four new species of Diptera from those regions—*Culicx pinguis*, *Laphria columbica*, *Cuterebra approximata* and *Eurygaster septentrionalis*.

Note.—Walker's descriptions are notoriously bad. Osten Sacken, Catalogue, 1878, preface, p. xvi, has enlarged a little upon this subject. It was the policy of Osten Sacken and Loew not to adopt Walker's names unless, as is very rarely the case, the description contains some positive mark of identification. In their view, it was preferable to describe as a new species in doubtful cases. Some recent American workers have followed a different principle, and recognized Walker's species on mere preponderance of evidence; this I take it is especially true of Mr. Coquillett. It is desirable that each student of the order examine the descriptions for himself, and form his own conclusions as to the recognizability of any particular one. Furthermore, it is very desirable, in case that one of these specific names be resurrected, that the species be redescribed at the same time; otherwise in most cases other entomologists will be completely in the dark as to the species referred to, and confusion will be increased. This pending a fuller knowledge of the type, which must some time be arrived at.

Walsh, Benjamin D.

Insects Injurious to Vegetation in Illinois. Rock Island, 1861 (pamphlet).

Exorista (Senometopia) militaris n. sp. (syn. of *Winthemia quadripustulata*).

On certain Remarkable or Exceptional Larvae, etc. Boston Society of Nat. Hist., IX, 286-308, 1864.

Mydas fulvipes n. sp.

On the Insects, coleopterous, hymenopterous and dipterous. Inhabiting Galls of certain Species of Willow. Proceedings of the Entomological Society of Philadelphia, III, 543-644 and VI, 223-288; 1864 and 1868.

Numerous species of Cecidomyiidae and their galls, new.

First Annual Report on the Noxious Insects of the State of Illinois. Transactions of the Illinois State Horticultural Society, appendix. Chicago, 1868.

Trypetia pomonella n. sp., now referred to *Rhagoletis*.

Mr. Couper's Thorn-leaf Gall. Canadian Entomologist, I, 79, 1869.

Cecidomyia crategi-bcdeguar n. sp.

Larvæ in the Human Body. American Entomologist, II, 137, 1870.

"Contains description of three larvæ of Homalomyia, designated as *H. wilsoni*, *leydii* and *prunivora*. Perfect insect not described." O. S.

Washburn, F. L.

Hessian Fly Reared in the Laboratory. Canadian Entomologist, XXXV, 316; Nov., 1903.

Existence of a second brood proved in Minnesota.

Gastrophilus epilepsalis. Canadian Entomologist, XXV, 320; Nov., 1903.
A species identified as this affecting man as a *subcutaneous* parasite;

evidently an error of determination, as stated by Banks in the succeeding number of the journal.

Webster, F. M.

Report on Buffalo Gnats. Bull., 14, Division of Entomology, Dept. of Agriculture, 29-30; 1887.

On the breeding-places, etc., of Simuliidae in the south; no new species.

Notes on a species of Necrophagous Diptera. Insect Life, II, 356-358 and 370-372; 1890.

Habits of *Conicera* sp.

Larvæ of a Crane-fly Destroying Young Wheat in Indiana. Insect Life, III, 12-14; Aug., 1890.

An undetermined Tipulid.

Report on Several Species of Crane-Flies Infesting Meadows, etc. Bull. 26, Div. of Entomology, Dept. of Agriculture, 65-74; 1892.

Tipula costalis mentioned as one.

Methods of Oviposition in Tipulidae. Bulletin Ohio Exp. Sta., Technical Ser., vol. 1, No. 3, p. 151-154, figs.; 1893.

Habits of *Tipula bicornis* LOEW MS. and *Pachyrhina* sp.

A Dipterous Gall-maker and Its Associates. Bull. Ohio Exp. Sta., Tech. ser., 1, 154, 155; 1893.

Gall and Associates of *Lasioptera muhlenbergiae* MARTEN.

Notes and Observations on Several Species of Diptera. Canadian Entomologist, XXX, 18, 19; Jan., 1898.

Notes on seven species, mostly reared.

Species of Diptera Reared in Indiana in 1884-1889. Proc. Indiana Acad. Science, 1898, 2 pp.

These rearings had already been reported in Division of Entomology bulletins, No. 10, new ser., and 7, Technical ser.

Some Species of Diptera Inhabiting or Frequenting the Wheat Fields of the Middle West. Canadian Entomologist, XXXII, 212, 213; July, 1900.

18 species reared from wheat and 34 species collected by sweeping in wheat fields; no new species.

Some Insects attacking the Stems of Growing Wheat, Rye, Barley and Oats. Bull. 42, Division of Entomology, 1903, 62 pp.

Treats, among other insects, of *Mermomyza americana*, *Oscinella carboaria* and *soror*.

Weed, C. M.

Note on the Horn Fly. American Naturalist, Jan., 1893, 63.

Weed, H. E.

Note on the Natural Habitat of the Screw-Worm Fly. Canadian Entomologist, XXIII, 243, 1891.

Westcott, Oliver S.

The Distribution of Some North American Syrphidae. Entomological News, VIII, 190, 191; October, 1897.

Locality of collection given for 56 species.

Westwood, John O.

On Diopsis, a Genus of Dipterous Insects, etc. Trans. of Linnean Soc., XVII, 283-313 and 543-550, 2 col. plates; 1837.

Sphyracephala brevicornis is reproduced, description and figure, from Say.

Insectorum novorum exoticorum ex ordine dipterorum Descriptiones. London and Edinburgh Philosophical Magazine, ser. 3, vi, 280, 281 and 447-449; 1835.

Bittacomorpha n. g.; *Lepidophora aceriformis* GRAY, *Pangonia macroglossa* and *Gynoplistia annulata*, all from North America.

Insectorum nonnullorum novorum (ex ordine Dipterorum) Descriptiones. Annales Soc. Ent. de France, iv, 681-685; 1835.

Limnobiorynchus canadensis n. sp., from Canada.

Note.—I have not seen this and the preceding; from data in Osten Sacken, Hagen, etc., they seem to be the same article, the latter having one species added.

Description of Some New Exotic Aeroceride. Transactions of the Entomological Society [of London], v, 91, 1848.

Six new species from North America.

Synopsis of the Dipterous Family Midasiidae, with Descriptions of numerous Species. Arcana Entomologica, i, two col. plates; 1841-43.

Five new species from North America.

Generis Dipterorum Monographia Systropi. Guérin's Magazin de Zoologie, 1842.

Systropus fanoides n. sp., from Mexico.

Diptera nonnulla exotica Descripta. Trans. Ent. Society, v, 231, 1850.

Ceria daphneus WALKER, from Jamaica, described and figured.

Notæ DipteroLOGICÆ. Monogr. of the Genus *Systropus*, etc. Trans. Ent. Soc. London, 1876.

Reproduces description of *Systropus fanoides*.

Notæ DipteroLOGICÆ. Desc. of New Genera and Species of the Family Aeroceridae. Trans. Ent. Soc. London, 1876.

Pialoidea n. gen. for *Cyrthus magnus* from Georgia.

WHEELER, WM. M.

On Two New Species of Cecidomyiid Flies Producing Galls on *Antennaria plantaginifolia*. Proc. Wis. Nat. Hist. Society, April, 1889, 209-216.

Cecidomyia antennariae and *Asynapta antennariae* n. spp.; note on habits of adult, and on courtship of *Dolichopus plumipes*.

Descriptions of Some New North American Dolichopodidae. Psyche, 1890, 337-343; 355-362; 373-379.

Aphantotimus and *Peloropodes* n. gen. (the former syn. of *Thrypticus*); several new species.

The Supposed Bot-fly Parasite of the Box-turtle. Psyche, 1890, 403.

Drepanomyia (syn. of *Hypocharassus* MIK) *pruinosa* and *johsoni* (the latter a syn. of *H. gladiator* MIK).

New Species of Dolichopodidae from the United States. Proc. Cal. Acad. Sci., 3d series, I, 1-80, 4 plates; 1899.

Many new species; two new genera, *Parasyntomon* and *Nothosympycnus*.

A Genus of Maritime Dolichopodidae new to America. Proc. Cal. Acad. Sci., 3d ser., I, 145-152, 1 plate; 1899.

Aphrosylus predator, *direptor* and *grassator*, new, from California.

Anemotropisms and Other Tropisms in Insects. Archiv für Entwickelungsmechanik der Organismen, VIII, 373-381; 1899.

Several Diptera mentioned as illustrations.

The Genus Hypocharassus. Entomological News, XI, 423, 1900.

Synonymy of *Drepanomyia*.

Microdon Larvae in Pseudomyrma Nests. Psyche, July, 1901, 222, fig.

An undetermined species collected in Mexico.

An Extraordinary Ant-guest. American Naturalist, XXXV, 1007-1016, figs.; Dec., 1901.

Larva and puparium of an undetermined Phorid, commensal with the larva of *Pachycondyla harpax* at Austin, Tex.; one of the most interesting entomological articles I have ever seen.

Wheeler, Wm. M. and Melander, Axel L.

Biologia Centrali-Americanana. Diptera, vol. I. Family Empidæ, pp. 366-376; Dec., 1901.

Eighteen new species.

Whitney, C. P.

New Species of Tabanidæ. Canadian Entomologist, XI, 35-38, 1879.

Six species; see also note by Burgess, same volume, p. 80.

Wiedemann, C. R. W.

Diptera Exotica. Vol. I, Kiliæ, 1821.

This is a Latin work; on the completion of this first volume, it was decided to change to German, and all of this part is incorporated, in German, in his principal work, "Aussereuropäische Zweifl. Insekten."

Analecta Entomologica. Kiliæ, 1824.

Not seen. Contains 154 Diptera in all, comparatively few from North America.

Aussereuropäische Zweiflügelige Insekten. 2 vols., with 12 plates; Hamm, 1828 and 1830.

This great work contains very many North American Diptera. One of its objects was to elucidate the species of Fabricius, and nearly all the Diptera of that entomologist are redescribed; the original descriptions are also quoted in full. Another valuable feature is the redescription of a large number of Say's species, from material set on by Say himself, presumably typical in most cases. Wiedemann changed some of the specific names of

these; where there seemed to be no valid reason for the alteration, I have followed Say in nomenclature. In most cases of redescription, I omit the locality, as it is the same as in Say's description.

Achias, Dipterorum Genus a Fabricio conditum. Kiliæ, 1830; 16 pp., 1 plate.
Sphyracephala (*Achias*) *brevicornis* SAY, redesc. and figured.

Monographia Generis Midarum. Nova Acta Academie Naturae Curiosorum, xv, 19-56, 3 col. plates; 1831.

Four new species from North America.

Williston, Samuel Wendell.

An Anomalous Bombylid. Canadian Entomologist, Nov., 1879, 215.
 " *Anthrax* nov. sp., near *fuliginosa*."

Some Interesting New Diptera. Transactions of the Connecticut Academy of Arts and Sciences, iv, 243-246, 1880.

Rhynchocephalus sackenii, *Silvius pollinosus*, *Chrysops discalis*, new.

Eristalis tenax. Note on distribution, Canadian Entomologist, XIII, 76; Aug., 1881.

New or Little Known Genera of North American Syrphidæ. Canadian Entomologist, XIV, 77-82, 1882.

Three new genera, five species; superseded by his Synopsis of the Syrphidæ.

Drosophila ampelophila Loew. Canadian Entomologist, XIV, 138, 1882.

Note on habits and distribution.

Contribution to a Monograph of North American Syrphidæ. Proceedings of the American Philosophical Society, XX, 299-332, 1882.

23 new species, all reproduced in the Synopsis.

On the North American Asilidæ (Dasypogoninæ, Laphrinæ) with a New Genus of Syrphidæ. Transactions of the American Entom. Society, XI, 1-36, 3 pl.; 1883.

20 new species of Asilidæ; *Nausigaster punctulata* n. g. and sp. of Syrphidæ.

The North American Species of Nemestrinidæ. Canadian Entomologist, XV, 69-72, fig.; 1883.

Rhynchocephalus volaticus n. sp., from Fla.; table of species.

North American Conopidæ. Transactions of the Conn. Academy:

I. *Conops*. Vol. IV, 325-342, 1 plate; 1883.

II. *Stylogaster*, *Dalmannia*, *Oncomyia*. Vol. VI, 87-94; 1884.

III. Conclusion. Vol. VI, 377-394, 1 plate; 1885.

In these three numbers are tables of genera and species, old species redescribed, and several new; practically a monograph of the family.

The Screw-worm Fly. Psyche, 1883, 132.

Notes on *Chrysomya macellaria* FAB.

Eine Merkwürdige neue Syrphiden-Gattung. Wiener Entom. Zeitung, III, 185, 186, 1884.

Euccratomyia pergandei n. g. and sp., from D. C.

Note on the Genus *Merapioidus* Bigot. Wiener Entom. Zeitung, III, 282, 1884.

Dipterous Larvæ from the Western Alkaline Lakes, and their Use as Food.

Transactions Conn. Academy, VI, 83-86; July, 1884.

Ephydria californica PACK., described, larva figured.

- Bibliography of North American Diptera. Kans. Univ. Quart., iv, 129-144 and 199-204; Jan. and Apr., 1896.
- Fissicorn Tachinidae. Kans. Univ. Quart., iv, 171, 172, fig.; Jan., 1896.
 Notes on *Dichocera* and others.
- A New Genus of Hippoboscidae. Entomological News, vii, 184, 185; June, 1896.
Brachypteromyia femorata n. g. and sp., from Wyoming; in a note at end, 12 genera not previously reported from North America are mentioned.
- Manual of North American Diptera. Second edition, rewritten and enlarged. New Haven, Conn., 1896; James T. Hathaway. Pp. liv. and 167.

Anatomy of Diptera, bibliography, table of families, definition of each family, and table of North American genera for each family except Tachinidae and Dexiidae. A few generic names are altered, or new ones proposed, on account of preoccupation. I have omitted all references to this work, except where names are changed, because I assume that all workers with Diptera are familiar with it. To the beginner it is indispensable, and to the advanced worker a great convenience.

On the Diptera of St. Vincent. Transactions of the Entomological Society of London, 1896, pt. 3, pp. 253-446, 7 plates.

Many new genera and species from this island, which is far south in the Lesser Antilles.

Diptera Brasiliana. iv. Kans. Univ. Quarterly, vi, 1-12; Jan., 1897.

Notes on *Lipochata*; some new genera and species from Grenada, W. I.

On the Genus Thilipsogaster Rond. Psyche, March, 1899, 331, 332.

The American species are not of this genus.

Notes and Descriptions of Mydaide. Kansas Acad. Science, 1897, 53-58.

Mydas quadrilineatus and *Ectypus towensis*, new North American species; a few South American species.

Note.—An admirable feature of Williston's work, which does not show fairly in the above list, is the attention he has given to identifying and redescribing the species of other writers. In all his longer papers this is a prominent part, frequently occupying as much space as the new descriptions, and requiring more time than they in preparation.

Woodworth, Chas. W.

Gonia senilis Will., Psyche, v, 43, 1889.

Zetterstedt, J. W.

Diptera Scandinaviæ, disposita et descripta. Lundæ, 1842-1860.

While this work treats only of Scandinavian species, there are many which are circum-polar. Zetterstedt's earlier work, *Insecta Lapponica*, is mostly reproduced in this.

ERETMOPTERA.

- KELLOGG, Biol. Bull., I, 82, 1900.
browni KELLOGG, loc. cit., figs.—Monterey, Cal.
Note.—The family name Eretmopteridae was proposed for this species by Professor Kellogg, but he has since informed me that the larval stages are essentially the same as in Chironomidae, a family which already includes at least one genus with rudimentary wings; and I have his sanction in placing the species here.

CULICID.E.

The discovery that mosquitoes convey malaria, yellow fever, filariasis, and possibly still other diseases, from one human being to another, deserves to rank with the greatest achievements of science. The immediate result, very naturally, has been an immense increase of interest in this family of Diptera, so that new

work is at present being published very rapidly. Theobald's Monograph, noticed below, gives a bibliography up to Feb., 1903, including early articles on the relation of mosquitoes to malaria. I enumerate a few important publications.

On Malaria, etc.

- Riley, Amer. Nat., xvii, 549, May, 1883, mentions the theory of Dr. A. Kink, Columbia University, that mosquitoes cause malaria.
 Nuttall, Dr. Geo. H., Johns Hopkins Hospital Reports, viii.
 Finlay, Chas. J., M.D., Psyche, July, 1899.
 Berkeley, Dr. W. N., N. Y. Medical Record, Dec. 23, 1899.
 Woldert, Dr. Albert, Jour. Amer. Medical Assn., Feb. 10, 1900.
 Burns, Dr. Wm. B., Memphis Medical Monthly, March, 1900.
 Ross, Major Ronald, Nature, March 29, 1900.
 Manson, Dr. Patrick, Popular Science Monthly, July, 1900.
 Celli, "Malaria According to the New Researches," trans. by Eyre. Longmans, Green and Co. London, 1900.
 Howard, "Mosquitoes." McClure, Phillips & Co. New York, 1901.
 Howard, Yearbook of Dept. of Agriculture, 1901, 177-192; Farmers' Bulletin 155, Dept. of Agriculture.

On Classification.

- F. Lynch Arribalzaga, Revista Mus. de la Plata, i, 345-417, 4 pl., 1891; the Argentine species.
 Ficalbi, Bull. Soc. Ent. Ital., 1892-1896, a series of articles revising the European species; he published another general work in vol. xxxi, 1899.
 Lintner, 12th N. Y. Rept., 319-335, 1897, popular account.
 Coquillett, Circular No. 40, n. ser., Div. of Ent.—a brief synopsis of the species known in the United States; published in a second edition, with a slight addition; also published in Bull. 25, n. ser., Div. of Ent.
 Herrick, Bull. 74, Miss. Ex. Sta.
 Garman, Bull. 96, Ky. Ex. Sta.
 Lugger, 2d Rept. Ent. Minn., 182-195, with good figs.
 Giles, Handb. of Gnats. John Bale Sons and Danielsson, Limited. London, 1900.

A second edition, entirely rewritten, was published in 1902; in its new form, the systematic part is mainly an abridgement of the following.

- Theobald, A Monograph of the Culicidæ. Printed by the British Museum, 1901-3. Three volumes, with many figures and maps, and a fourth volume of plates, mostly colored. Contains a vast amount of information on distribution, habits in larval and mature stages, etc. The systematic part is based on the collections in the British Museum.

Johannsen, Bull. 68, N. Y. State Mus., 388-429, 1903, tables of genera of larvæ, pupæ and adults, etc.

On Larvæ.

- Dyar, Proc. Ent. Soc. Wash., v, 51 and 145, 1902 and 1903, analytical tables of the known larvæ from the United States.
 Kellogg, Ent. News, x, 102, length of larval period.
 Smith, Ent. News, xiii, 198, notes on hibernating stage in various species.
 Morgan and Dupree, Bull. 40, n. ser., Div. of Ent., 88, notes on hibernation and development of several species.
 See also recent smaller papers by Coquillett, Smith and Dyar, as mentioned under the various species.

Note.—The nomenclature adopted is generally that of Theobald.

ANOPHELES.

MEIGEN, Syst. Besch., I, 10, 1818.

DESOVIDY, Mem. Soc. Hist. Nat. Paris, III, 410, 1827.

HESPERODES.

COQUILLETT, Ent. News, 1900, 429.

Note.—This genus is said to be "near *Hesperinus*," which Osten Sacken, after seeing the type, placed in the Bibionidae.

johsoni COQUILLETT, loc. cit.—Delaware Water Gap, N. J.

CECIDOMYIDÆ.

There are peculiar difficulties in the task of properly representing this family in the present Catalogue. On account of the fact that many species make galls on plants, we encounter here a mixture of botanical and zoological science, which has tended to separate the study of the Cecidomyiidae from that of the other Diptera. Only those who have made a special study of the family are at all informed about it. Unfortunately, not one of the present generation of American entomologists has given this special attention.

To make matters ten-fold worse, the European specialists in Cecidomyiidae

have come to a practical unanimity in accepting certain principles of nomenclature which radically change the generic names used by Osten Sacken, who followed Loew. The change hinges on the application of the name *Cecidomyia* (disregarding for the time being the new genera which have naturally come into existence), and will be found fully discussed in the following papers:

KARSCH, Revision der Gallmücken, Münster, 1878, 10-20.

OSTEN SACKEN, Catalogue, 215, note 1, 1878.

RÜBSAAMEN, Berl. Ent. Zeitsch., XXXVII, 324-327, 1892.

KIEFFER, Annales Soc. Ent. France, 1900, 436.

OSTEN SACKEN, Ent. Mo. Mag., 1901, 40-43.

The practical effect of the changes adopted by Karsch, Rübsaamen and Kieffer is to apply the name *Cecidomyia* to the *Diplosis* of Osten Sacken's Catalogue, and to divide up his *Cecidomyia* between *Rhabdophaga* and *Dasyneura*. As nearly all the species in the family were referred to *Cecidomyia* and *Diplosis* in Osten Sacken's Catalogue, the adoption of the changed nomenclature will leave few members of the family in the same genera to which Osten Sacken referred them.

Realizing the immense practical disadvantage of such an overturning of names, I should have been well content to let the problems of nomenclature lie in abeyance; but they have been already threshed out in Europe, and the conclusions reached and put in use there cannot be ignored.

After much consideration, I can find no better course to follow than to adopt the generic distribution of Kertész, in his Catalogus Dipterorum, vol. II. Not having much knowledge of the family myself, and not being able to consult an American authority on it, I have carried out this plan. I take occasion to remark, however, that Osten Sacken thoroughly disapproves of the changes, and has given, in the last reference above, his reasons for his views.

Some of the species still included under *Cecidomyia* doubtless belong to other established genera, but are not yet sufficiently described to allow of a positive reference; in fact, many of the species need further study, and at best the present scheme must be considerably modified by more thorough investigation. No family of the Diptera offers greater inducements to a worker who will patiently carry on the biological and systematic study of it conjointly.

The status of those names which have been applied to larvæ and galls only, or to pupæ, larvæ and galls, or even to galls alone, need not be settled at the present time. I have placed all such names in a division by themselves. My opinion is that when the adult is at last described, the same old specific name should be used, unless impracticable, but that thenceforth the description of the adult should be regarded as the real description of the species. Meanwhile, it is very convenient, and thoroughly in accord with the objects of nomenclature, that the provisional name should stand.

A few species described since Kertész have been added, in harmony with his general distribution.

Cross-references have not been thought necessary, considering the small size of the family.

The European literature is voluminous; Kieffer gives over 800 references. His Monographie des Cécidomyides d'Europe et d'Algérie, in Annales Soc. Ent. France, 1900, 181-472, 30 plates, is indispensable to any student of the family. I add here only a few references.

COMSTOCK, Dept. Agric. Rept., 1880, 270, 271, list of references on parasitic and inquilinous species.

BRAUER, Zweifl. d. Kaiserl. Mus., III, 1883, 20 and 53, references to descriptions of larvæ.

MIK, Wien. Ent. Zeit., xvi, 284-289, on mounting and describing specimens.

OSTEN SACKEN, Western Dipt., 192, 1877, describes several galls without naming them.

MRS. SLOSSON, Ent. News, vii, 238, a species attaching itself to wing of a lace-wing fly to be carried about.

SMITH, Dept. Agric. Rept., 1884, 396-398, a species infesting pears in Conn.

RILEY and HOWARD, Ins. Life, iii, 294, note on a species destroying buds of roses grown under glass—see *Neocerata rhodophaga*.

MAYETIOLA.

KIEFFER, Miscellanea Entomologica, Jan., 1896; Wien. Ent. Zeit., xv, 89, 1896.

Note.—The only North American representative is the well-known "Hessian Fly," so-called from the supposition that it was introduced from Europe along with the Hessian soldiers in the Revolution. It has uniformly been referred to the genus *Cecidomyia* in the past by American writers. The larva injures young wheat plants; it is found between the stalk and the sheathing portion of one of the lower leaves.

The literature is very voluminous. Kertész, in his Catalogue, II, 76, gives three pages of references; Osborn, in Bull. 16, mentioned below, gives a far more lengthy list. I give a few of the early references, paying more attention to the newer publications, since the time of Osborn's paper. From the first, the articles are biological and economic in their scope. The European references are omitted here.

destructor SAY, Jour. Acad. Sci. Phil., 1, 45, pl. III, f. 1-3; Compl. Works, I, 4—Eastern U. S.

FITCH, Amer. Quart. Jour. Ag. and Sci., IV, 244-264, 1846; V, 1-27, 1847; revised and republished, Trans. N. Y. State Ag. Soc., 1846, 316-373, 1 pl.; 3d N. Y. Rept., 133-144; 7th Rept., 819-830, pl. III, f. 2, 3; 8th Rept., 685, note.

PACKARD, Bull. 4, U. S. Ent. Comm.; full life hist. and figs.; the same with additions, 3d Rept. U. S. Ent. Comm., 198-248, pl. IV, V; also in the appendix to the third Report is a transl. of an article by Löw and Wagner.

FORBES, Ill. Rept., 1885, 14; 1886, 21-34; 1890, 54-63.—Ill. and Mississippi Valley generally.

LINTNER, 5th N. Y. Rept., 263, notes.

RILEY, 5th Mo. Rept., 116, same fig. and note.

PACKARD, Guide to Study of Ins., 376, fig.

- bedeguar** WALSH, Canad. Ent., I, 79; Proc. Ent. Soc. Phil., VI, 266 (*cratægi-bedeguar*).—Ill.; on *Crataegus tomentosa*, the thorn-apple.
- brachynteroides** OSTEN SACKEN, Mon. N. A. Dipt., I, 198.—D. C.; on *Pinus inops*.
- brassicoides** TOWNSEND, Psyche, 1893, 490 (*bigeloviae-brassicoides*).—N. M., on *Bigelovia graveolens*.
- carbonifera** OSTEN SACKEN, Mon. N. A. Dipt., I, 195.—D. C., on leaves of *Solidago*. N. J.—Smith Cat.
- caryæcola** OSTEN SACKEN, Mon. N. A. Dipt., I, 192.—D. C., on *Carya*. N. J.—Smith Cat.
- citrina** OSTEN SACKEN, Trans. Amer. Ent. Soc., III, 53.—N. Y., on *Tilia americana*.
- clavula** BEUTENMÜLLER, Bull. Amer. Mus. Nat. Hist., IV, 1892, 269, pl. xv, f. 5.—N. Y., on *Cornus* sp. N. J.—Smith Cat.
- TOWNSEND, Proc. Ent. Soc. Wash., II, 390, gall.—Va.
- culmicola** MORRIS (Miss), Proc. Acad. Nat. Sci. Phil., IV, 194.—Pa.; in wheat stalks.
- HARRIS, Ins. Inj. to Veget., 582.
- cynipsea** OSTEN SACKEN, Mon. N. A. Dipt., I, 193.—D. C., on *Carya*.
- deserta** PATTON, Canad. Ent., XXIX, 247 (*Cecidomyia-celtis deserta*).—Conn.
- erigerontis** BRODIE, Biol. Rev. of Ont., I, 1894, 13-15 (*Diplosis*—gen. ref. taken from adult).—Toronto, Can.; on *Erigeron canadense*.
- erubescens** OSTEN SACKEN, Mon. N. A. Dipt., I, 193.—D. C.; on *Quercus*.
- farinosa** OSTEN SACKEN, Mon. N. A. Dipt., I, 204.—D. C.; on leaves of blackberry, *Rubus*.
- BRODIE, Biol. Rev. of Ont., I, 1894, 110, ec. at Toronto (*Diplosis*). N. J.—Smith Cat. (*Lasioptera*).
- glutinosa** OSTEN SACKEN, Mon. N. A. Dipt., I, 193.—D. C.; on *Carya*.
- hageni**, n. sp.: I apply this term to the gall described, but not named, by Hagen, Canad. Ent., 1881, 37, on *Aristolochia siphon*.
- helianthi** BRODIE, Biol. Rev. of Ont., I, 1894, 44-46.—Toronto, Can.; in axils of leaves of *Helianthus decapetalus* and *divaricatus*.
- holotricha** OSTEN SACKEN, Mon. N. A. Dipt., I, 193; Cat., 216, note.—D. C., on *Carya*. N. J.—Smith Cat.
- hordoides** WALSH, Proc. Ent. Soc. Phil., III, 599 (*salicis-hordoides*).—Rock Id., Ill.; on *Salix humilis*.
- impatientis** OSTEN SACKEN, Mon. N. A. Dipt., I, 204; Amer. Ent., II, 63, fig. of gall.—D. C.; deforms flowers of *Impatiens*. N. J.—Smith Cat.
- inopis** OSTEN SACKEN, Mon. N. A. Dipt., I, 196 (*pini-inopis*).—D. C.; forms a resinous cocoon on *Pinus virginiana* (*inopis*). N. J.—Smith Cat. (*Diplosis*).
- liriiodendri** OSTEN SACKEN, Mon. N. A. Dipt., I, 204.—D. C.; on leaves of *Liriodendron*.
- HAGEN, Canad. Ent., XVIII, 159, note on paedogenesis. N. J.—Smith Cat.
- monardæ** BRODIE, Biol. Rev. of Ont., I, 1894, 109-111 (*Diplosis monardi*, or perhaps a *Lasioptera*).—Toronto, Canada; gall on *Monarda fistulosa*.
- majalis** OSTEN SACKEN, Trans. Amer. Ent. Soc., III, 53 (*quercus-majalis*); Mon. N. A. Dipt., I, 204 (id.).—D. C.
- PACKARD, 5th Rept. U. S. Ent. Comm., 207 (id.), gall and larva; on pin oak, *Quercus palustris*.
- niveipila** OSTEN SACKEN, Mon. N. A. Dipt., I, 199, gall.—D. C.; on oak of several species. N. J.—Smith Cat.

- nodulus** WALSH, Proc. Ent. Soc. Phil., III, 599 (*salicis-nodulus*).—Rock Id., Ill.; gall on *Salix longifolia*.
- nucicola** OSTEN SACKEN, Trans. Amer. Ent. Soc., III, 53.—N. Y.; in the husks of nuts of *Hicoria*.
- ocellaris** OSTEN SACKEN, Mon. N. A. Dipt., I, 199.—D. C.; larva in depression on under side of leaf of *Acer rubrum*.
- Note*.—Comstock, Rept. Dept. Agric., 1881-2, 202, pl. xvii, describes the adult as a *Sciara*. But Mik, in Verh. Zool.-bot. Ges., 1883, 190-192, considers this an error of rearing, the *Sciara* coming from the earth in the breeding cage. The same view is held by Brauer, Zweifl. d. Kaiserl. Mus., III, 46, and by Osten Sacken, 2d edit. of his Characters of Larvae of Mycetophilidae, Heidelberg, 1886, postscript, p. 27.
- N. J.—Smith Cat.; Mich.—J. M. A.
- pellex** OSTEN SACKEN, Mon. N. A. Dipt., I, 199.—D. C.: galls on leaves of *Fraxinus americana*. N. J.—Smith Cat.
- persicoides** OSTEN SACKEN, Mon. N. A. Dipt., I, 193; Cat., 216, note.—D. C.: on *Hicoria*. N. J.—Smith Cat.
- poculum** OSTEN SACKEN, Mon. N. A. Dipt., I, 201; Cat., 216, note (probably inquinilous in the gall of a Cynipid of *Quercus*).—D. C.
- FITCH, 2d N. Y. Rept., No. 40, "Oak Spangles."
- N. J.—Smith Cat.
- pomum** WALSH and RILEY, Amer. Ent., I, 106, f. 85, gall (*vitis-pomum*).—Ill.; on *Vitis cordifolia*.
- RILEY, 5th Mo. Rept., 114-116, figs. and notes.
- N. J.—Smith Cat.
- pubibunda** OSTEN SACKEN, Mon. N. A. Dipt., I, 202.—D. C.; on leaves of *Carpinus caroliniana*.
- racemicola** OSTEN SACKEN, Mon. N. A. Dipt., I, 196.—D. C.; larvae among racemes of *Solidago*.
- rigidae** OSTEN SACKEN, Mon. N. A. Dipt., I, 189, gall desc. and name changed.
- FITCH, Amer. Quart. Jour. Agric. and Sci., I, 263 (*salicis*, preoc.).—N. Y.; makes a swelling at the tip of twig of *Salix rigida* and *lucida*.
- WALSH, Proc. Ent. Soc. Phil., III, 595, abstr. of Fitch.
- N. J.—Smith Cat.
- salicifoliae** OSTEN SACKEN, Proc. Ent. Soc. Phil., VI, 220.—Canada; on *Spiraea salicifolia*.
- salicum** COCKERELL—the gall so mentioned is that of a sawfly of the genus *Pontania*, with "little or no doubt";—Ckll. *in litt.*
- sanguinolenta** OSTEN SACKEN, Mon. N. A. Dipt., I, 192.—D. C.; on *Hicoria*.
- N. J.—Smith Cat.
- serotinae** OSTEN SACKEN, Trans. Amer. Ent. Soc., III, 346.—N. Y.; on *Prunus serotina*. N. J.—Smith Cat.
- symmetrica** OSTEN SACKEN, Mon. N. A. Dipt., I, 200.—D. C.; on *Quercus*.
- triticoides** WALSH, Proc. Ent. Soc. Phil., III, 598; VI, 225 (*salicis-triticoides*).—Rock Id., Ill.; on *Salix cordata*.
- tubicola** OSTEN SACKEN, Mon. N. A. Dipt., I, 192; Cat., 216, note.—D. C.; on *Hicoria*.
- N. J.—Smith Cat.
- tulipiferae** OSTEN SACKEN, Mon. N. A. Dipt., I, 202.—D. C.; on *Liriodendron*.
- N. J.—Smith Cat.
- umbellicola** OSTEN SACKEN, Trans. Amer. Ent. Soc., III, 52 and 347.—N. Y.; N. J.; on *Sambucus racemosa*, among the umbels.

- urnicola OSTEN SACKEN, Canad. Ent., Nov., 1875.—Trenton Falls, N. J.; on *Urtica gracilis*.
 verruca WALSH, Proc. Ent. Soc. Phil., III, 606 (*salicis-verruca*); VI, 226.—Rock Id., Ill.; on leaf of *Salix humilis* and *discolor*.
 verrucicola OSTEN SACKEN, Canad. Ent., Nov., 1875.—New England; on *Tilia americana*. N. J.—Smith Cat.
 viticola OSTEN SACKEN, Mon. N. A. Dipt., I, 202.—D. C.; on *Vitis*.
 RILEY, Amer. Ent., II, 28 and 113, fig. (both as *vitis-lituus*).
 N. J.—Smith Cat.

ZETTERSTEDT, Dipt. Scand., IX, 3414, 1850 (*Simulia*).

SCHINER, Fauna Austr., II, 363, 1864 (*Simulium*).

OSTEN SACKEN, Amer. Entomologist, II, 220, 1870, transformations; Berl. Ent. Zeitschr., XXXVII, 1892, 452, discussion of family characters.

COQUILLET, Bull. 10, new series, Div. of Ent., 66-69, table and brief desc. of N. A. species.

MEINERT, Eucephale Myggelarver, 458, 1886, bibliog. of transformations and study of same in *S. ornatum*, with pl. IV, f. 115-127.

Note.—The following references relate to biology, etc., of species which were not specifically determined:

RILEY, Dept. Ag. Rept., 1884, 340-345, pl. IX, f. 1, 2, 3.

RILEY and HOWARD, Insect Life, brief items and extracts from correspondence, Vol. I, 15, 61, 143, 224, 314; II, 7-11; IV, 143; VII, 426.

HOWARD, Insect Life, I, 99, habits of a species at Ithaca, N. Y.

TOWNSEND, Trans. Amer. Ent. Soc., XX, 45, describes early stages and habits of a species inhabiting Grand Canon of the Colorado; figs.

HAGEN, Can. Ent., XIII, 150, notes on a larva; Ent. Mo. Mag., 1883, 254, note.

LUGGER, 2d Rept. Ent. Minn., 1896, 172-182.

KELLOGG, Psyche, Feb., 1901, 166, says larvae live largely on diatoms.

argus WILLISTON, Dipt. of Death Valley Exped., 253.—Argus Mts., Cal.

COQUILLET, Proc. Wash. Acad. Sci., II, 394, regards as a synonym of *vittatum*. Johannsen, *in litt.*, does not.

WILLISTON, Biologia, Dipt., I, 223, oc. in Guerrero, Mex.

bracteatum COQUILLET, Bull. 10, n. ser., Div. Ent., 69.—Mass., Cal.

cinereum BELLARDI, Saggio, I, 13.—Mex.

TOWNSEND, Proc. Cal. Acad. Sci., IV, 593, note on oc. in Lower Cal. (Mex.).

decorum WALKER, List, I, 112.—Martin Falls, Canada.

COQUILLET, Bull. 10, n. ser., Div. Ent., makes this a synonym of *vittatum* ZETTERSTEDT; but the description seems to contradict this.

fulvum COQUILLET, Proc. U. S. N. M., XXV, 96. Mentioned in the following as *ochraccum* WALKER:

COQUILLET, Bull. 10, n. ser., Div. Ent., oc. in Col. and Mont., etc.; Proc. Wash. Acad. Sci., II, 393, oc. in Alaska and British Col.

COCKERELL, Ent. News, VIII, 100, oc. in N. M.

BAKER, Ent. News, VIII, 172, oc. in Col., and notes.

glaucum COQUILLET, Proc. U. S. N. M., XXV, 97.—Kansas City, Mo.

griseum COQUILLET, Bull. 10, n. ser., Div. Ent., 69.—Col.

hirtipes FRIES., Mon. Simuliari., 17, pl. I, f. 1, 1824.—Europe.

MEIGEN, Syst. Beschr., VI, 311 and 312 (*rufipes* and *hirtipes*).

ZETTERSTEDT, Dipt. Scand., IX, 3426.

SCHINER, Fauna Austr., II, 368.

JOHANNSEN, Ent. News, XIV, 14, oc. in N. Y.

Idaho—Johannsen *in litt.*

invenustum WALKER, List, I, 112.—Martin Falls, Canada. See also *pecuarum*.

irritatum LUGGER, 2d Rept. Ent. Minn., 1896, 177, f. 145, 146, no description.—Minn.

meridionale RILEY, Rept. Dept. Agriculture, 1886, 513, pl. VII and VIII. Same distribution and habits as *pecuarum*; called the Turkey Gnat.

TOWNSEND, Psyche, July, 1891, 107 (*occidentale*).—New Mex. [Coq.]

COQUILLET, Bull. 10, n. ser., Div. Ent., 68, fig.—Mass., Nebr., Texas.

RILEY and HOWARD, Insect Life, I, 14; said to cause the death of thousands of chickens and turkeys yearly in Va.

 slightly doubtful.
pulcher LOEW, Cent., III, 16.—D. C.
 TOWNSEND, Trans. Amer. Ent. Soc., XXII, 55, oc. at Las Cruces, N. M.,
 and notes.
 N. J.—Smith Cat.; White Mts., N. H.—Slosson.
 Note.—Loew's description of the female should be ignored. I examined the types at the request of Mr. Kahl, and as he expected, found one female of a *Pachygaster*, and both the male and female of a species belonging to a different genus, the eyes of the male being separated. These are all referred to in one way or another under the description of the female, which consequently becomes useless to science.

LOPHOTELES.

- LOEW, Berl. Ent. Zeitsch., 1858, 110.

ACANTHOMERA.

WIEDEMANN, Dipt. Exot., 60, 1821; Auss. Zw., I, 107, 1828.

THUNBERG, Acta Gothob., III, 1819 (*Pantophthalmus*).

MACQUART, Hist. Nat. Dipt., I, 217, 1834.

BIGOT, Bull. Soc. ent. de France, 1880, no. 1, p. 5; Annales, 1882, 455 (*Megalemyia*, in part). [O. S.]

argyropasta BIGOT, Bull. Soc. ent. de France, 1880, no. 1, p. 5; Annales, 1882, 455 (*Megalemyia*).—Panama.

OSTEN SACKEN, Biologia, Dipt. 1, 64, says this is the male of *Acanthomera seticornis*, but as Bigot, in Bull. Soc. ent. France, 1886, CLXVIII, still maintains both the species and the genus *Megalemyia*, I allow the former to stand.

bellardii BIGOT, described by Bellardi, Saggio, App., 16, f. 11, from Mexico, seems never to have been published by Bigot.

bigoti BELLARDI, Saggio, App., 16, f. 10.—Oaxaca, Mex.

championi OSTEN SACKEN, Biologia, Dipt., 1, 67, pl. III, f. 16.—Nicaragua and Panama.

BELLARDI, Saggio, 1, 76 (*picta* WIEDEMANN).—Mexico. [O. S.]

TOWNSEND, Proc. Cal. Acad. Sci., IV, 595.—Costa Rica.

crassipalpis MACQUART, Dipt. Exot., Suppl. II, 27, pl. 1, f. 3.—Guatemala.

picta WIEDEMANN, is not known from North America; for Bellardi's reference see *A. championi*.

rubriventris BIGOT, Bull. Soc. ent. de France, no. 1, p. 5; Annales, 1882, 456.—Guatemala.

seticornis WIEDEMANN, Auss. Zw., 1, 108.—Brazil.

MACQUART, Dipt. Exot., 1, 1, 168, pl. XX, f. 1; Suppl. II, 27.—Brazil; Guatemala; may be the male of *crassipalpis*. See also *argyropasta*.

tabaninus THUNBERG, Acta Soc. Gothob., III, 1819, III, pl. VII, f. 2 (*Pantophthalmus*).—West Indies.

WIEDEMANN, Auss. Zw., 1, 110, quotes orig. desc.

RHAPHIORHYNCHUS.

WIEDEMANN, Dipt. Exot., 59, 1821; Auss. Zw., 1, 105, 1828.

planiventris WIEDEMANN, Dipt. Exot., 60; Auss. Zw., 1, 106, pl. 1, f. 4; II, 622.—Surinam, Guiana.

MACQUART, Dipt. Exot., 1, 1, 170, pl. XX, f. 3; Suppl. II, 27, pl. 1, f. 3 (*Ac. crassipalpis*, in the latter place).—Brazil and Guatemala. [O. S.]

BELLARDI, Saggio, App., 16, f. 10 (*Ac. bigoti*).—Oaxaca, Mex. [O. S.]

BIGOT, Annales, 1882, 458 (*crassipalpis* MACQ.).

OSTEN SACKEN, Biologia, Dipt., 1, 66.—Panama.

Note to the Family Acanthomeridae.—There exists no reason known to me for maintaining the name *Acanthomera* against the apparently prior name *Pantophthalmus*, the adoption of which would involve a change of the family name to correspond. But I have not access to Thunberg's work, and it seems a very good rule to give the benefit of the doubt to current names.

LEPTIDÆ.

(Inclusive of Nylophagidae and Cenomyidae.)

BIGOT, Bull. Soc. Zool. France, XII, 4, 1887, table of genera of the world, restricted sense.

Jamaica—Johnson.

[*serveillei* MACQUART, identified by Coquillett from Porto Rico and Bahamas in Proc. U. S. N. M., xxii, 251, was never described; Macquart has a figure of a wing with the name *Exoprosopa servillei*, on pl. xvi, Dipt. Exot., ii. As there is no locality, and the other figures on the plate are from all parts of the world, it seems to me undesirable to try to resurrect the species.]

APIOCERIDÆ.

The relations of the group, and the question of family rank, have been exhaustively discussed in the following papers:

OSTEN SACKEN, Berl. Ent. Zeitsch., xxvii, 1883, 287.

WILLISTON, Psyche, 1888, 100, and Kans. Univ. Quart., I, 101, 1893, two plates.

APIOCERA.

WESTWOOD, London and Edinb. Philos. Mag., 1835; Arcana Ent., I, 50, 1841.

MACQUART, Dipt. Exot., I, 1, 78, 1838 (*Tapinocera*).

MACQUART, Dipt. Exot. Suppl., II, 47, 1847 (*Pomacera*).

PHILLIPPI, Verh. Zool.-Bot. Ges., 1865, 702, pl. xxv, f. 26 (*Anypenus*).

augur OSTEN SACKEN, Biologia, Dipt., I, 2.—Presidio, Mex.

haruspex OSTEN SACKEN, West. Dipt., 283.—Yosemite, Cal. There is a correction of the desc. in Berl. Ent. Zeitsch., xxvii, 300.

COQUILLETT, Psyche, 1885, 244.

Wash.—J. M. A.

APOMYDAS.

COQUILLETT, Canad. Ent., xxiv, 314, 1892 (*Apomidas*).

trochilus COQUILLETT, Canad. Ent., xxiv, 315.—Merced Co., Cal.

RHAPHIOMYDAS.

OSTEN SACKEN, West. Dipt., 281, 1877.

TOWNSEND, Proc. Cal. Acad. Sci., IV, 601, table of species.

acton COQUILLETT, West. Amer. Scientist, VII, 84.—Los Angeles Co., Cal.

TOWNSEND, Proc. Cal. Acad. Sci., IV, 602.—Sonora, Mex.

episcopus OSTEN SACKEN, West. Dipt., 282.—Cal., or perhaps Lower Cal.

TOWNSEND, Proc. Cal. Acad. Sci., IV, 603.—Lower Cal. The comparison with *episcopus* made by Coquillett in describing *acton* refers to *mellifex* instead.

mellifex TOWNSEND, Proc. Cal. Acad. Sci., IV, 604.—Lower Cal.

COQUILLETT, West American Scientist, VII, 84 (*episcopus*).—Los Angeles Co., Cal. [Townsend.]

xanthos TOWNSEND, Proc. Cal. Acad. Sci., IV, 606.—Lower Cal. Also in Trans. Amer. Ent. Soc., xxvii, 161, oc. in Las Cruces, N. M.

DOLICHOPODIDÆ.

LOEW, Mon. N. A. Dipt., vol. II, 1864 (in Smithsonian Miscellaneous Collections, No. 171), is a monograph which is still useful, although it must be studied in connection with the later works. The earlier descriptions are quoted and discussed in this monograph.

BIGOT, Annales, 1890, 261, article with table of genera of the world.

Note.—The arrangement in subfamilies, much of the synonymy, and some notes, are the result of my own study of the family, which has been a favorite with me for fourteen years.

AGONOSOMINÆ.

PSILOPODINUS.

BIGOT, Annales Soc. Ent. France, 1890, 269.

? BIGOT, Annales Soc. ent. France, 1859, 215 (*Oariostylus*, *Megistostylus*, *Mesoblepharius*, *Condylostylus*, *Eurostomerus*, *Dasypsilopus*, *Heterop-silopus*, *Aedipsilopus*).

LOEW, Mon. N. A. Dipt., II, 229 (*Psilopus*), 1864.

? BIGOT, Annales Soc. ent. France, 1890, 261-269 (*Spathipsilopus*, *Eudasypus*, *Amblypsilopus*, *Tylochatus*, *Oariopherus*).

ALDRICH, Kans. Univ. Quart., II, 47, 1895 (*Psilopus* in restricted sense); Biologia Centrali-Americanana, Dipt., I, 350, 1901, table of American species (id.); Canad. Ent., 1904, 246, nomenclature.

Note.—As the species up to 1902 have all been referred to under the name *Psilopus*, it will be unnecessary to repeat it in each reference.

MELANDER, *Mon. Empid.*, I, 332, 1902 (in litt. he includes his species of *Holoclera* also).

Notc.—There is great divergence of views between Coquillett and Melander as to the limits of *Microphorus*, *Anthalia*, and *Euthyneura*. Coquillett, in *Proc. Ent. Soc. Wash.*, V, 263, has distributed the species according to his ideas. I have been guided mainly by Melander's views, communicated to me in letters.

atratus COQUILLETT, see *Euthyneura*.

bilineatus MELANDER, *Mon. Empid.*, I, 334, f. 99 (*Holoclera*).—Opelousas, La.

crocatus COQUILLETT, see *Euthyneura*.

drapetoides WALKER, *List.*, III, 489.—Martin Falls, Canada.

MELANDER, *Mon. Empid.*, I, 332, quotes desc.

flavipilosus COQUILLETT, see *Euthyneura*.

gilvihirtus COQUILLETT, see *Euthyneura*.

obscurus COQUILLETT, *Proc. Wash. Ent. Soc.*, V, 268.—Franconia, N. H.

palliatus COQUILLETT, *Jour. N. Y. Ent. Soc.*, X, 140 (*Sciodromia*).—Tabasco, Mex.

ravidus COQUILLETT, *Revis. Empid.*, 409.—S. Cal.

MELANDER, *Mon. Empid.*, I, 333 (*Holoclera*).

sycophantor MELANDER, *Mon. Empid.*, I, 334 (*Holoclera*).—Idaho.

EUTHYNEURA.

MACQUART, *Annales*, 1836, 517.

SCHINER, *Fauna Austr.*, I, 82, 1862.

MELANDER, Mon. Empid., I, 256, def. and table, 1902; the latter amended, p. 347; in litt. includes *Anthalia* as a synonym, following Schiner.

COQUILLETT, Proc. Ent. Soc. Wash., V, 263, 1903, radically disagrees and does not recognize the genus from North America.

aperta MELANDER, Mon. Empid., I, 348.—Cloudercroft, N. M.

atrata COQUILLETT, Proc. Wash. Acad. Sci., II, 412 (*Microphorus*) ; Proc. Ent. Soc. Wash., V, 263, refers to *Anthalia*.—Kodiak, Alaska.

MELANDER, Mon. Empid., I, 333 (*Holoclera*).

atrides MELANDER, Mon. Empid., I, 349.—Los Angeles Co., Cal.

bucinator MELANDER, Mon. Empid., I, 348.—Pa.

bulbosa MELANDER, Mon. Empid., I, 349.—Chester Co., Pa.

crocata COQUILLETT, Proc. Wash. Acad. Sci., II, 413 (*Microphorus*).—Sitka.

Gen. ref. by Melander, in litt.

flava COQUILLETT, Proc. Ent. Soc. Wash., V, 268 (*Anthalia*).—Mt. Washington, N. H.

SLOSSON, Ent. News, XIV, 266, habits of adult.

flavipilosa COQUILLETT, Proc. Wash. Acad. Sci., II, 413 (*Microphorus*) ; Proc. Ent. Soc. Wash., V, 263, same gen. ref.—Lowe Inlet, Br. Col.

MELANDER, Mon. Empid., I, 257.

gilvihirta COQUILLETT, Proc. Ent. Soc. Wash., V, 268 (*Microphorus*).—Franconia, N. H.

Gen. ref. by Melander, in litt.

nura MELANDER, Mon. Empid., I, 349.—Mass.

stentor MELANDER, Mon. Empid., I, 348.—Cloudercroft, N. M.

stigmalis COQUILLETT, Proc. Ent. Soc. Wash., V, 268 (*Anthalia*).—Port Renfrew, B. C.

CYRTOMA.

MEIGEN, Syst. Beschr., IV, I, 1824.

SCHINER, Fauna Austr., I, 76, 1862.

MELANDER, Mon. Empid., I, 335, 1902, def. and table of species.

COQUILLETT, Proc. Ent. Soc. Wash., V, 246, proposes to replace *Cyrtoma* with *Bicellaria* Macq. I do not feel sure of his data, and hence make no change.

femorata LOEW, Cent., V, 60.—N. H.

MELANDER, Mon. Empid., I, 335.

halteralis LOEW, Cent., II, 46.—D. C.

MELANDER, Mon. Empid., I, 335.—Wis.

longipes LOEW, Cent., II, 47.—Ill.

MELANDER, Mon. Empid., I, 336, f. 71.—Mass., N. H., Wis., Ill., Wyo., N. M.

White Mts., N. H.—Slosson; Pa.—O. S.

pilipes LOEW, Cent., II, 48.—Ill.

COQUILLETT, Proc. Wash. Acad. Sci., II, 412, oc. in Kukak Bay and Popof Id., Alaska.

MELANDER, Mon. Empid., I, 336.

White Mts., N. H.—Slosson.

procera LOEW, Cent., V, 70.—Sitka, Alaska.

MELANDER, Mon. Empid., I, 335.

RHAMPHOMYIA.

MEIGEN, Syst. Beschr., III, 42, 1822.

SCHINER, Fauna Austr., I, 96, 1862.

Coquilletti, Revis. Empid., 410, 1895, table of species; in Proc. Ent. Soc. Wash., v, 252, he proposes to substitute *Macrostomus* Wied. for *Rhamphomyia*. I do not adopt this, as there is considerable risk of error in the old determination upon which it depends.

PHORIDÆ.

BECKER, Die Phoriden, in Abhandlungen d. K. K. Zool.-Bot. Ges., I, 1-100, 5 plates, 1901, is an admirable monograph of the European members of the family.

BRUES, Monograph of the N. A. Phoridæ, in Trans. Amer. Ent. Soc., xxix, 331-404, 5 plates, describes the genera of the world and all the N. A. species, with a new generic arrangement. It is dated 1903, but really appeared in January, 1904. This would exclude it from the present catalogue, which closes with Jan. 1, 1904, but I deem it necessary to make an exception here, in order to avoid having this part of the work out of date on publication. There are full tables of genera and species, etc.; it is a very valuable work.

OSTEN SACKEN, Ent. Mo. Mag., sec. ser., XIII, 204, 1902, discusses the position of this family.

PHORA.

LATREILLE, Précis. car. gén. Ins., 1796; Hist. nat. Crust. et Ins., III, 464, 1802, and XIV, 394, 1804. In 1802 he gives *Musca aterrima* as type.

fasciatus LOEW, Cent., x, 59.—Texas.
HOUGH, Proc. Boston Soc. Nat. Hist., xxix, 78, type redesc.
KERTÉSZ, Wien. Ent. Zeitung, xix, 270, would change name to *locwi*, because there was once a *fasciatus* described, which turned out to be a synonym. I should strongly object to admitting the principle.
flavicornis WILLISTON, Biologia, Dipt., iii, 88.—Guerrero, Mex.
GIGLIO-TOS, Ditt. del Mess., ii, 71, note on male.—Tuxpango, Mex.
flavitarsis WILLISTON, Biologia, Dipt., iii, 87.—Guerrero, Mex.

HOUGH, Proc. Boston Soc. Nat. Hist., xxix, 82, type redesc.
White Mts., N. H.—Slosson; Axton, N. Y.—M. and H.
See *nitidiventris*.
houghi of Smith's Cat. is a manuscript name;—Ent. News, xii, 96 and xiv, 107.
houghi of KERTÉSZ, see *lateralis*.
lateralis WALKER, Dipt. Saund., 216.—N. A.
COQUILLETT, Proc. Acad. Nat. Sci. Phil., 1895, 331, refers to *Prothecus*.
KERTÉSZ, Wien. Ent. Zeitung, 1900, 244, refers to *Pipunculus*, and changes name to *houghi* on account of preoccupation.
VERRALL, Brit. Flies, viii, 120, shows that there was no preoccupation, as Meigen's *lateralis* is a synonym of *maculatus* WALKER.
St. Augustine, Fla.—Johnson.
nigricornis ADAMS, Kans. Univ. Sci. Bull., ii, 36.—Atherton, Mo.
nigripes LOEW, Cent., vi, 75.—Pa.
HOUGH, Proc. Boston Soc. Nat. Hist., xxix, 79, type redesc.
N. J.—Smith Cat.; White Mts., N. H.—Slosson.
nitidiventris LOEW, Cent., vi, 72.—D. C.
HOUGH, Proc. Boston Soc. Nat. Hist., xxix, 82, type redesc.; may be the female of *fuscus*.
White Mts., N. H.—Slosson; Montreal—Chagnon.
opacus WILLISTON, see *Verrallia*.
pallipes JOHNSON, Ent. News, xiv, 107.—Wildwood, N. J.
politus WILLISTON, Trans. Ent. Soc. London, 1896, 351, pl. xi, f. 88.—St. Vincent, W. I.
similis HOUGH, Proc. Boston Soc. Nat. Hist., xxix, 83.—Tifton, Ga.; Ala.
N. J.—Smith Cat.

subopacus LOEW, Cent., vi, 74.—D. C.

WILLISTON, Biologia, Dipt., iii, 88, oc. and note.—Guerrero, Mex.

HOUGH, Proc. Boston Soc. Nat. Hist., xxix, 79, type redesc.

Montreal—Chagnon.

subvirescens LOEW, Cent., x, 58.—Texas.

? WALKER, Trans. Ent. Soc., iv, 150 (*translatus*).—U. S. [Hough, with a ?]

HOUGH, Boston Soc. Nat. Hist., xxix, 84.—New Bedford, Mass.; Tifton, Ga.; Opelousas, La.

Montreal—Chagnon.

willistoni KERTESZ, Wien. Ent. Zeit., xix, 1900, 244, change of name.

WILLISTON, Biologia, Dipt., iii, 88 (*aculeatus*, preoc.); Trans. Ent. Soc. Lond., 1896, 351 (id.).—Tabasco, Mex.; St. Vincent, W. I.

xanthopodus WILLISTON, Biologia, Dipt., iii, 87.—Guerrero, Mex.

VERRALLIA.

MIK, Wien. Ent. Zeit., xviii, 137, 1899.

BECKER, Berl. Ent. Zeitsch., xlvi, 1897, 93 (*Prothecus* ROND.).

Note.—According to Mik, loc. cit., Rondani made an error of identification, and the species he named as the type is not *auctus*, but has an acuminate third antennal joint. This antennal character is mentioned in the definition, hence *Prothecus* could not be used for the present group, in which the lack of a point on the third antennal joint is one of the principal characteristics.

opaca WILLISTON, Trans. Amer. Ent. Soc., xiii, 295 (*Pipunculus*).—Wash.

HOUGH, Proc. Boston Soc. Nat. Hist., xxix, 77, refers to *Prothecus*, in Becker's sense.

KERTÉSZ, Wien. Ent. Zeitung, xix, 244, refers to *Verrallia*.

SYRPHIDÆ.

WILLISTON, Synop. N. A. Syrphidæ. Bulletin of The United States National Museum, No. 31. Washington, 1886, xxx and 335 pages, with 12 plates. The largest and most complete family monograph yet published on North American Diptera.

VERRALL, British Flies. Syrphidæ, etc. Gurney and Jackson, London, 1901. 690 pages, portrait and many excellent text figures. Includes also in an appendix of 121 pages a full catalogue and bibliography of the British representatives of the three families described, which are the Platopezidæ, Pipunculidæ and Syrphidæ. This massive volume is an encyclopedia on the three families indispensable to the advanced worker. Many of the British species and most of the genera occur also in America.

CHAGNON, G., Études Préliminaires sur les Syrphides de la Province de Québec. Chicotini, Quebec, 1901, 75 pages. Originally published in parts in "Le Naturaliste Canadien," 1901. I quote the separate edition. It is a convenient and useful compilation on the commoner species of that region.

LASIOPHTHICUS.

RONDANI, Dipt. Ital. Prod., i, 51, 1856; ii, 137, 1857.

OSTEN SACKEN, West. Dipt., 325, 1877; Cat., 1878, 244 (both *Catabomba*).

BIGOT, Bull. Soc. Ent. France, 1882, No. 2, p. 20, syn.

WILLISTON, Synop. N. A. Syrph., 62, 1886 (*Catabomba*).

VERRALL, Brit. Flies, viii, 333, 1901 (id.).

Note.—I dissent from the conclusions of Osten Sacken and Verrall in adopting Rondani's name here. In the first reference above, Rondani says, "Spec: typ: *Musca pyrastri* LINN." and mentions no other species. Hence the proper procedure, in case the genus is ill conceived, is to revise its definition, rather than to make its type *the type* of another genus. I here use *Lasiophthicus* as if this had been done, exactly in the sense of *Catabomba*.

pyrastri LINNÉ, Syst. Nat., 10th ed., 594 (*Musca*); Fauna Suec., 2d ed., 448 (id.).—Europe.

ŒSTRIDÆ.

BRAUER, Monographie der Œstriden, Vienna, 1863, is the great classic work on this family.

BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., IV, 158 and VI, 180, tables of genera of the world.

BRAUER, Zweifl. d. Kaiserl. Mus., III, 36, table of genera, based on larvae of the third stage.

BRAUER, Denkschr. d. Kaiserl. Akad. Wiss., Math.-Naturwiss. Classe, LXIV, 259–282, 1 pl., has a fascinating article on the descent of the Œstridæ and on the elephant bot, *Cobboldia elephantis*, which may be brought to the United States in elephants from India.

TOWNSEND, Proc. Ent. Soc. Wash., II, 94, 1891, gives tables of genera, both for larvae and adults, from Brauer.

OSBORN, Bull. Div. Ent., No. 5, notes on *Gastrophilus* and other bots.

HUNTER, Nebraska Bd. of Hort., 189, 291–300, popular illustrated account of bots.

AUSTEN, Annals and Mag. Nat. Hist., 6th ser., XV, 391, 1895, table of genera of *Cuterebra*.

The following references have not been assigned to any genus:

Ground-squirrel bot: RILEY and HOWARD, Insect Life, IV, 147, extract from correspondence, on a new species from Kansas, not *emasculator*.

Bots affecting Man: BLANCHARD, Annales Soc. ent. de France, 1892, full summary of American cases.

RILEY and HOWARD, Ins. Life, V, 2, brief review of foregoing; p. 58, addition—notes on same subject.

See also under *Dermatobia*.

Botfly of Cat: RILEY and HOWARD, Insect Life, VI, 206, extract from correspondence on, in North Carolina; p. 327, two more cases, in N. Y. and Mo.

Botfly of Rabbit: RILEY and HOWARD, Insect Life, III, 21, extract from correspondence on, affecting jack-rabbits in Texas. See also *Cuterebra*.

GASTROPHILUS.

LEACH, On the Genera and Species of Eproboscideous Insects, 1817.

MEIGEN, Syst. Beschr., IV, 174, 1824 (*Gastrus*).

SCHINER, Fauna Austr., I, 390, 1862.

BRAUER, Mon. Œstriden, 53, 1863, full biology, table of species, etc.

[**epilepsalis** FRENCH, Canad. Ent., 1900, 203, fig.; 1904, 83.—Ill.

ALDRICH, Canad. Ent., 1900, 318, rejects species.

Note.—Described from a larval specimen 2 mm. long, passed by a boy who had had epileptic spasms for four years!]

WASHBURN, Canad. Ent., XXXV, 320, case of a subcutaneous human parasite,—almost certainly a different species.

- BANKS, Canad. Ent., XXXV, 333, the original was not an *Œstrid* larva at all.
- equi** CLARK, Trans. Linn. Soc., III, 226, pl. XXIII, f. 7-9, 1788 (*Œstrus equi*).—Europe.

DERMATOBIA.

BRAUER, Verh. Zool.-Bot. Ges., 1890; Mon. Oestriden, 251, 1893

No North American species have been described. The following papers relate to this genus:

SAY, "On the South American species of *Oestrus*, which inhabits the Human Body," Jour. Acad. Sci. Phil., II, 354, 1822; Compl. Works, II, 32.

RUDOLPH MATAS, M.D., paper by, on species infesting man in New Orleans; reprinted, with figs., in Insect Life, I, 76.

OSBORN, Insect Life, I, 226, quotes another account from Miss.

TOWNSEND, Psyche, Aug., 1892, 200, describes a larva from *Lepus calotis*; afterward refers it to *Bogeria*, q. v.

TACHINIDÆ.

Note.—The classification adopted follows closely that of Coquillett, Revision of the Tachinidæ, Bulletin of Division of Entomology, Technical series, No. 7, 1897. This work seems to embody a far clearer and more consistent idea of the genera than any other general work on the American species of the family. It includes, however, only the fauna of the United States, and that no farther than seen by the author. This has necessitated my adding a large number of

genera and species, which I have endeavored to distribute in accordance with the classification in the work mentioned. I cannot hope to have made a perfect success of this, considering the difficulty of the family.

The work of Brauer and Bergenstamm, *Vorarbeiten zu einer Monographie der Muscaria schizometopa*, forming parts IV, V and VI of the series called *Zweiflugler des Kaiserlichen Museums zu Wien*, is an elaborate and extensive work, characterized by a minute subdivision of the group into numerous so-called families, sections, super-genera, and genera. Although it shows an immense amount of patient and faithful study, it is vitiated by a failure to grasp the natural divisions between groups of the same category. Hence it must be used with caution, and much experience is necessary before one can judge of its authoritativeness in a particular case. The table contains many illusory characters, and the usefulness of the work is further marred by a succession of addenda, modifying the system in numerous parts, and making it still more difficult to follow.

The work of Townsend shows itself to have been powerfully influenced by the one just mentioned; hence there is a serious confusion of genera, and in some instances the same species is described several times under different genera, or in the same genus. The worst instance of this will be found under *Myiophasia anca*. This was not the result of carelessness but of a too narrow splitting up of genera and species, in the attempt to follow Brauer and Bergenstamm. The specific descriptions of Townsend are conscientious and faithful, and among the most recognizable of any in the family.

The extensive article by Van der Wulp on the Mexican and Central American fauna, published in vol. II of the Diptera in *Biologia Centrali-americana*, goes to the other extreme in the matter of genera, and the large genera in it are without exception heterogeneous collections, which can at present hardly be placed consistently in the system here adopted.

The descriptions by Bigot are in every way objectionable, almost always referred to the wrong genus, and seldom containing the essential data. Most fortunately, the types of nearly all the species have been examined by Brauer, who has elucidated them in accordance with his system in three articles in *Sitzungsberichten der Kaiserlichen Akademie der Wissenschaften (Mathematisch-Naturwissenschaftlichen Classe, Bd. CVI, CVII and CVIII)*. This makes it possible to arrange them fairly well in the present work.

The following tables of genera may be consulted:

TOWNSEND, Proc. Ent. Soc. Wash., II, 92, 96; Trans. Amer. Ent. Soc., XIX, 134.

VAN DER WULP, Biologia, Dipt., II, 5 and 41.

COQUILLET, Revision Tach., 30; this is most important.

The synonymy adopted by Coquillett in his Revision has been followed rather closely for the species included in that work, without giving credit in the references.

To facilitate reference through the index, I mention the following cases where the genus might not otherwise be found:

Argyrophylax rostrata Coq. has been placed in *Siphonostomia*.

Ceromasia ROND. is a synonym of *Masiccra*; but only *chrysoccephala* and *zonata* of Bigot have been placed there. His *abbreviata*, *pictigaster*, *quadrivittata* and *spinipes* will be found in *Hypostoma*, while his *castanifrons* has been referred to *Prosphecia*.

Chætolyyga is a synonym of *Winthemia*; but the species of Bigot will be found under *Exorista*, *Hypostoma*, *Phorocera* and *Winthemia*.

Dimorphomyia calliphoroides BIGOT, Bull. Soc. Ent. France, 1885, has been found on examination of the type to consist of the head of a Syrphid glued to the body of a Muscid. See BRAUER, Sitzungsbericht Kaiserl. Akad., cvii, 14. We may say at least that it was admirably named!

Eggonia VAN DER WULP, mentioned by Brauer and BERGENSTAMM, Zweifl. Kaiserl. Mus., vi, 104, lacks a specific name for the type, and must have been a manuscript name on some of Van der Wulp's material.

Eurigaster MACQ. is a synonym of *Exorista*, but *E. septentrionalis* WALKER will be found under *Euphorocera claripennis*.

Fabricia DESV. is a synonym of *Echinomyia*, but Bigot's *F. infumata* will be found under *Archytas bicolor*.

Loewia EGGER: the species of Townsend all fall under *Myiophasia cœnæ*.

Lophosia setigena THOMSON has been placed under *Clausicella*.

Lydella doryphoræ RILEY will be found under *Phorocera*, although the genus is a synonym of *Exorista*.

Melanosphora diabroticæ SHIMER is a *Celatoria*.

Micropalpus is a synonym of *Linnaemyia*, but some of the species are placed under *Efalphus* and *Cuphocera*.

Oplisa albibafacies BIGOT is referred to *Pseudodexia* by Brauer, and *O. nigrafacies* to *Medina*.

Pachychæta jarowchewskyi PORTSCHINSKY, from Russian America, is listed by B. and B. among the material in the Vienna Museum; but I have found no other reference to it.

Phasia atripennis SAY is referred to *Xanthomelana*, and *jugatoria* to *Trichopoda pennipes*.

Podotachina americana B. B. is referred to *Tachina mella*, and *P. vibrissata* B. B. to *Euphorocera claripennis*.

Pseudogermaria georgiae B. B. is referred to *Distichona*.

Ptilocera americana MACQ. is referred to *Phyto*.

Pyrrosia ochracea BIGOT is referred to *Œstrophasia*.

Siphoniomyia melas BIGOT is referred to *Trichophora analis*.

Thysanomyia inermis BIGOT, mentioned by Johnson, Dipt. of Florida, may be *Blepharipeza inermis*, but I am not certain.

The species of **Tryphera** described by Townsend all go in *Polidea*.

Viviana citrina BIGOT will be found under *Chatona longiseta*; *georgica* in *Biomyia*; and *rufopygata* in *Leskia*.

Wahlbergia is a synonym of *Besseria*, but Townsend's *atripennis* is a *Xanthomelana*.

Xysta didyma LOEW is a *Clytiomyia*.

cinerea VAN DER WULP, see *Euphorocera*.

claripennis MACQUART, see *Euphorocera*.

comstocki WILLISTON, in Scudder's Butterflies of New England, III, 1922.—No locality; reared by Riley from *Megathymus yuccae*.

TOWNSEND, Psyche, 1893, 467, bred by Forbes from *Lophyrus* sp. and *Pyrausta penitalis* GROTE.

COQUILLETT, Revis. Tachin., 104.—D. C., S. C., Mo. N. J.—Smith Cat.

cylindrata VAN DER WULP, Biologia, Dipt., II, 82.—Guerrero, Mex.

demylus WALKER, see *Admontia*.

doryphoræ RILEY, 1st Mo. Rept., III (*Lydella*).—Mo.; reared from *Doryphora decemlineata* SAY.

PETTIT, Bull. 186, Mich. Expt. Sta., and Rept. Mich. Bd. of Agric. for 1901, 189, reared from same beetle in Northern Mich.; good fig.

COQUILLETT, Revis. Tachin., 104.—N. Ill., Mo., Col., N. M.; bred by Riley from *Vanessa antiopa* L.

- edwardsii** WILLISTON, see *Euphorocera claripennis*.
- erecta** COQUILLET, Proc. U. S. N. M., xxv, 112; Revis. Tachin., 103 (*parva* BIGOT).—Ark., S. Cal.; bred from *Tortrix citrana* FERN.
- facialis** COQUILLET, Revis. Tachin., 105.—San Diego, Texas.
- flavicauda** VAN DER WULP, Biologia, Dipt., II, 83.—Guerrero and Mexico City, Mex.
- fulviceps** VAN DER WULP, Biologia, Dipt., II, 80.—Guerrero and Orizaba, Mex.
- immaculata** VAN DER WULP, Biologia, Dipt., II, 82.—Guerrero, Mex.
- leucaniae** COQUILLET, Revis. Tachin., 104.—D. C., Ky., Tenn.; bred from *Leucania unifascia* HAW. and *Loxostege similalis* GUEN.
- linearis** VAN DER WULP, Biologia, Dipt., II, 86.—Guerrero, Mex.
- lophyri** TOWNSEND, Trans. Amer. Ent. Soc., xix, 28).—Ottawa, Canada; reared from *Lophyrus abictis*.
- Note.*—Coquillett has made this a synonym of *Euphorocera claripennis*, but from an examination of the type I think it should stand.
- macra** VAN DER WULP, Biologia, Dipt., II, 84.—Tabasco, Mex.
- COQUILLETT, Revis. Tachin., 103.—Utica, Miss.
- melanoceps** BIGOT, see *Metadoria barbata*.
- ? **melobosis** WALKER, List, IV, 743 (*Tachina*); Dipt. Saund., 200 (*T. addita*).—Fla.; U. S.
- COQUILLET, Revis. Tachin., 105, syn.; not seen, but perhaps a *Phorocera*.
- muscaria** VAN DER WULP, Biologia, Dipt., II, 83.—Tabasco, Mex.
- nigrifrons** VAN DER WULP, Biologia, Dipt., II, 81.—Guerrero, Mex.
- nigrita** VAN DER WULP, Biologia, Dipt., II, 77, pl. III, f. 11.—Costa Rica.
- parva** BIGOT, Annales, 1888, 260.—Rocky Mts.
- BRAUER, Sitzungsbericht d. K. Akad., cvi, 19, refers to *Paradoria*, from type.
- Note.*—For the *parva* of Coquillett's Revision, see *erecta*.
- parvula** VAN DER WULP, Biologia, Dipt., II, 78.—Orizaba, Mex.
- GIGLIO-TOS, Ditt. del Mess., III, 41, notes.—Mex.
- prisca** WALKER, see *Cryptomeigenia theutis*.
- promiscua** TOWNSEND, see *Frontina frenchii*.
- puer** WILLISTON, Trans. Ent. Soc. Lond., 1899, 354, pl. XI, f. 91.—St. Vincent, W. I.
- rufilabrum** VAN DER WULP, Biologia, Dipt., II, 79.—Guerrero, Mex.
- COQUILLET, Revis. Tachin., 103.—Newark, N. J.
- N. J.—Smith Cat.; Battle Creek, Mich.—J. M. A.
- saunderii** WILLISTON, in Scudder's Butterflies of New England, III, 1022.—No locality; bred by Riley from chrysalis of *Argynnis cybèle*.
- COQUILLET, Revis. Tachin., 104.—Alameda Co., Cal.
- scutellaris** VAN DER WULP, Biologia, Dipt., II, 85.—Guerrero, Mex.
- setigera** VAN DER WULP, Biologia, Dipt., II, 84.—Vera Cruz and Tabasco, Mex.
- sobrina** VAN DER WULP, Biologia, Dipt., II, 84.—Tabasco, Mex.
- sternalis** COQUILLET, Proc. U. S. N. M., xxv, 112.—N. H., Me., Idaho.
- tenebricosa** VAN DER WULP, Biologia, Dipt., II, 77.—Guerrero and Tuxpano, Mex.
- tenuiseta** MACQUART, Dipt. Exot., Suppl. I, 106.—Cayenne, S. A.
- VAN DER WULP, Biologia, Dipt., II, 483, notes and oe.—Guerrero, Mex.
- theutis** WALKER, see *Cryptomeigenia*.
- tortricis** COQUILLET, Revis. Tachin., 103.—Mich., Mo.; bred by Gillette from a Tortricid.
- xanthura** VAN DER WULP, Biologia, Dipt., II, 80 and 483.—Guerrero, Mex.

CHÆTOGENA.

- RONDANI, Dipt. Ital. Prod., III, 175, 1859.
 BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., IV, 94, 1889 (emended into *Setigena*) ; VI, 110, 1893 (*Setigena*).

metopia BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., IV, 161; V, 340; VI, 120.—Tacubaya and Merida, Mex.
 VAN DER WULP, Biologia, Dipt., II, 158 (*Didyma mæsta*).—Several places in Guerrero, Mex. [B. B.]

HYPERTROPHOCERA.

- TOWNSEND, Trans. Amer. Ent. Soc., XVIII, 360, 1891.
parvipes TOWNSEND, Trans. Amer. Ent. Soc., XVIII, 360; Canad. Ent., XXIV, 166, o.c. and note.—Las Cruces, N. M.

FRONTINA.

- MEIGEN, Syst. Beschr., VII, 247, 1838.
 RONDANI, Dipt. Ital. Prod., IV, 36, 1861.
 SCHINER, Fauna Austr., I, 496, 1862.
 BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., V, 334, 1891 (*Achætoncura*) ; 340 (*Thysanomyia*) ; VI, 115, 1893 (*Parafrontina*).
 COQUILLETT, Revis. Tachin., 105, 1897, notes and syn.
acroglossoides TOWNSEND, see *Chactogædia analis*.
aletiae RILEY, Canad. Ent., XI, 162 (*Tachina*). Bred from *Alectia argillacea* HUEB.
 COMSTOCK, Rept. Commr. of Agric., 1879, 303 (*Tachina fraterna*).—Ala.; bred from *Alectia argillacea* HUEB.; the description is quoted by Riley, 4th Rept. U. S. Ent. Comm., Appendix, p. 109.
 COQUILLETT, Revis. Tachin., 107.—Toronto, Canada; Mass. to Fla. and S. Cal.; reared from *Cerura* sp., *Dasylophha anguina* S. and A., *Halisidota maculata* HARR., *H. tessellata* S. and A., *Lagoa opercularis* S. and A., and *Orygia leucostigma* S. and A.
americana BIGOT, Annales, 1888, 260 (*Prosoptica*).—Mex.
 VAN DER WULP, Biologia, Dipt., II, 120 (*Proospherysa contigua*) ; 210, syn. —Morelos, Mex.
ancilla WALKER, Dipt. Saund., 299 (*Tachina*).—U. S.
 COQUILLETT, Revis. Tachin., 106.—Conn., Ga.
 N. J.—Smith Cat.
apicalis BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., VI, 115 (*Parafrontina*).—N. A.
archippivora WILLISTON, in Scudder's Butterflies of New England, III, 1923, pl. LXXXIX, f. 18 (*Masicera*).—Greeley, Col.; bred from *Danais archippus*.
 COQUILLETT, Revis. Tachin., 106.—Mich., Mo., Tex., Cal., Wash.; bred from *Agrotis ypsilon* ROTT., *Clisiocampa constricta* STRETCH, *C. pluvialis*

DYAR, *Danais archippus* FABR., *Laphygma flavimaculata* HARV., *Pyramis cardui* L., and *P. caryc* HUEB.

I reared this also from *Vanessa antiopa* at Moscow, Ida.—J. M. A. Beulah, N. M.—Skinner.

armigera COQUILLETT, Insect Life, I, 332 (*Masiccra*); Revis. Tachin., 106.—Los Angeles, Cal.; Allende, Mex. Bred from *Heliothis armiger* HUEB.

VAN DER WULP, Biologia, Dipt., II, 119 (*Prosphegysa comosa*).—Teapa, Mex.

Ormond, Fla.—Johnson.

[**chrysopygata** BIGOT, Annales, 1888, 84.—Mex.]

BRAUER, Sitzungsbericht d. K. Akad., cvi, 28, the types are a mixture of two species, of which the one corresponding to the description has no locality label.]

dubia WILLISTON, in Scudder's Butterflies of New England, III, 1924 (*Masiccra*).—No locality; bred by Riley from *Vanessa antiopa* L.

TOWNSEND, Trans. Amer. Ent. Soc., xix, 286 (*Masiccra sphingivora*).—Morgantown, W. Va.; bred by Hopkins from a Sphingid larva.

COQUILLETT, Revis. Tachin., 108, makes this a synonym of *violenta* WALKER, which seems to me uncommonly doubtful, so I do not follow it.—D. C.; bred from *Philampelus vitis* L.

? **dydas** WALKER, List, IV, 748 (*Tachina*).—Martin Falls, Canada.

COQUILLETT, gen. ref. from Walker's desc., with a doubt.

frenchii WILLISTON, in Scudder's Butterflies of New England, III, 1923, pl. LXXXIX, f. 23 (*Masiccra*).—Moosehead L., Maine; bred from *Papilio glaucus*.

BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., V, 334 (*Achactoneura hesperus*).—N. A.

TOWNSEND, Psyche, VI, 84 (*Phorocera promiscua*); Canad. Ent., xxiii, 206 (*Meigenia websteri*); Psyche, VI, 187 (*Masiccra schizuræ*); Trans. Amer. Ent. Soc., xix, 287 (*Masiccra datanarum*).—Orono, Maine, from *Clisiocampa sylvatica*; Lafayette, Ind.; Manhattan, Kans., from *Schizura unicornis*; N. Y., Canada and Minn., bred from *Datana* sp. and *Attacus polyphemus*.

RILEY, 5th Mo. Rept., 130; 7th Rept., 178; 8th Rept., 179 (*Tachina anonyma*, without description).—Mo. and Kans.; bred from *Anisota rubricunda*, *Caloptenus spretus*, and *Megathymus yuccæ*.

RILEY, PACKARD, and THOMAS, 1st Rept. U. S. Ent. Comm., 319, parasitic on Rocky Mt. Locust (*Tachina anonyma*).

COQUILLETT, Revis. Tachin., 107.—Canada; U. S. generally; list of twenty-nine hosts.

Note.—I examined types of *datanarum* and *schizuræ*; they seem to be the same.

fulvipalpis BIGOT, Annales, 1888, 263 (*Masiccra*).—Rocky Mts.

BRAUER, Sitzungsbericht d. K. Akad., cvi, 12, gen. ref. from type.

insularis WIEDEMANN . . . (*Tachina*).

BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., V, 334.—St. Thomas, W. I.

Perhaps a manuscript name of Wiedemann's.

irrequieta WALKER, List, IV, 789 (*Tachina*).—Nova Scotia. See note to *rileyi*.

rileyi WILLISTON, in Scudder's Butterflies of New England, III, 1924, pl. LXXXIX, f. 22, 24 (*Masiccra*).—No locality; bred by Riley from *Papilio cresphontes*.

- Coquillett**, Revis. Tachin., 108 (as *Tachina irrequieta* WALKER, which I do not consider recognizable).—Jacksonville, Fla.; bred from *Papilio thoas* L.
- rubentis** Coquillett, Proc. Acad. Nat. Sci. Phil., 1895, 310 (*Achætoncera*).—Revis. Tachin., 106.—Tifton, Ga.; Jacksonville and L. Worth, Fla.
- rufifrons** Roeder, Stett. Ent. Zeit., 1885, 346.—Porto Rico.
- rufostylata** Bigot, see *Prospherysa*.
- setipes** Coquillett, Proc. U. S. N. M., xxv, 112.—Brookings, S. D.
- tenthredinidarum** Townsend, Trans. Amer. Ent. Soc., xix, 285 (*Masicra*).—Ottawa, Can.; from sawfly.
- Coquillett, in the errata attached to the revised index to Revis. Tachin., p. 156, refers here. See *Masicra exilis*.
- violenta** Walker, List, iv, 788 (*Tachina*).—Nova Scotia. See note to *dubia*.

DEXIIDÆ.

- BIGOT, Revue d'Entomol., 1885, 266, table of all genera.
VAN DER WULP, Biologia, Dipt., II, 211, table of Mexican genera, 1891.
 BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., V, 1891.
 TOWNSEND, Trans. Amer. Ent. Soc., XIX, 1892, 273, table of N. A. genera.
VAN DER WULP, Tijdschr. v. Ent., XXVIII, 189, 1885, has a table of the long-legged genera, referring especially to those of Tropical America.
 Note.—Brauer and Bergenstamm published an extensive work in the same year as Van der Wulp, 1891. I am unable to settle the question of actual priority; but as Van der Wulp allowed Brauer and Bergenstamm to use his types as a matter of courtesy, and they attributed his genera to him, it would seem unwise to disturb this arrangement.

The ideas of the authors named above differ widely as to the limits and validity of genera; frequently they are hopelessly contradictory. The work of Brauer and Bergenstamm is obviously of a preliminary character, undergoing material change with each succeeding instalment, which makes it undesirable to follow it for sequence of genera.

The differences between Tachinidae and Dexiidæ are evanescent, and the prospect is that the families will ultimately be combined, or new family characters established. In the present work, most of the doubtful genera, if not in fact all of them, will be found in the Tachinidae.

The following notes may be grouped together, for convenience of reference:
Illigera ælops WALKER is a *Beskia*.

Illigeria corythus WALKER is *Xanthomelana atripennis*.

Illigeria helymus WALKER is a *Metachæta*.

Megerlea rufocaudata BIGOT goes in *Sarcophilodes*.

Oplisa albifacies BIGOT is a *Pseudodexia*.

Oplisa nigrifacies BIGOT; according to Brauer, Sitzungsbericht d. K. Akad., CVI, 32, the types include four species, referable to three genera.

Phorostoma appendiculata BIGOT is a *Myiomima*.

Phorostoma melanogaster BIGOT is *Sardiocera valida*.

Ptilodegeeria B. and B.; for the type species, see *Hypostena obumbrata* V. d. W.

Pyrrosia ochracea BIGOT is an *Oestrophasia*.

Sericocera pictipennis MACQ. is *Euantha dives*.

Tromodesia haemorrhoidalis BIGOT is *Leptoda atrifrons*.

- avida** WALKER, List, IV, 822.—Nova Scotia.
- basalis** WALKER, Dipt. Saund., 328.—U. S.
- carnaria** LINNÉ, does not occur in the United States, as I am positively assured by Dr. Hough, who has examined vast quantities of material without finding it. The following references undoubtedly refer to other species, probably several:
- HARRIS, Cat. Ins. Mass., oe. in Mass.
- RILEY, 7th Mo. Rept., 180, 181; 9th Rept., 95, parasitic on eggs of Rocky Mountain locust.
- RILEY, 1st Rept. U. S. Ent. Comm., 289, 323, 324, fig., attacking eggs of the same, and also parasitic on the growing insects; 4th Rept. U. S. Ent. Comm., 107, fig.; app., 109; parasitic on *Alectria xyloina* in the south.
- HUGO SUMMA, M.D., in St. Louis Med. and Surg. Journal, May, 1889, records a case of nasal myiasis in man due to *S. carnaria*; abstract in Insect Life, III, 40.
- WALTER B. JOHNSON, M.D., in Ophthalmic Record, 1892, account of larva in ear of man; abstract in Insect Life, IV, 341.
- LUGGER, 2d Rept. Ent. Minn., 1896, 155, fig.; habits, etc.
- chaetopygialis** WILLISTON, Trans. Ent. Soc. Lond., 1896, 366.—St. Vincent, W. I.
- chrysostoma** WIEDEMANN, Auss. Zw., II, 356.—W. I.
- SCHINER, Novara, 313, notes.—Brazil.
- cimbicis** TOWNSEND, Canad. Ent., XXIX, 126.—Brookings, S. D.; bred from *Cimex americana*.
- HUNTER (S. J.), Kans. Univ. Quart., VII, 206, reared from *Melanoplus differentialis* in Kansas; "Alfalfa, Grasshoppers and Bees," Bull. Ent. Dept., Univ. of Kans., 33, notes and fig.
- claripalpis** VAN DER WULP, Biologia, Dipt., II, 280.—Guerrero and N. Yucatan, Mex.
- comes** WALKER, Dipt. Saund., 323.—U. S.
- concinna** WILLISTON, Trans. Ent. Soc. Lond., 1896, 364.—St. Vincent, W. I.
- conclusa** WALKER, Trans. Ent. Soc., n. ser., V, 309.—Mex.
- conjungens** VAN DER WULP, Biologia, Dipt., II, 272.—Vera Cruz and Orizaba, Mex.
- consobrina** DESVOIDY, Myodaires, 344 (*Myophora*).—Philadelphia.
- cubensis** MACQUART, Dipt. Exot., II, 3, 106, pl. XII, f. 6.—Cuba.
- BIGOT, in Sagra's Cuba, 819.—Cuba.
- BRAUER, Sitzungsbericht d. K. Akad., CVII, 21, note.
- davidsonii** COQUILLETT, Insect Life, V, 24.—Los Angeles Co., Cal.; larvæ feeding on eggs of the spider *Phidippus opifex* McC.
- DAVIDSON, Insect Life, VI, 268, reared from egg sacs of *Argiope argentata*. Santa Catalina Id., Cal.
- debilis** VAN DER WULP, Biologia, Dipt., II, 279, pl. VII, f. 9.—Guerrero, Vera Cruz and Tabasco, Mex.
- deleta** VAN DER WULP, Biologia, Dipt., II, 282.—Guerrero, Mex.
- derelicita** WALKER, Dipt. Saund., 322.—U. S.
- despensa** WALKER, Trans. Ent. Soc., n. ser., V, 309.—Mex.
- diversinervis** VAN DER WULP, Biologia, Dipt., II, 274, pl. VII, f. 7.—Tabasco, Mex.
- diversipes** COQUILLETT, Proc. U. S. N. M., XXII, 255.—Porto Rico.
- effreneta** WALKER, Trans. Ent. Soc., n. ser., V, 309.—Mex.

- errabunda** VAN DER WULP, Biologia, Dipt., II, 278.—Guerrero and Tabasco, Mex.
fervida DESVOIDY, Myodaires, 341 (*Myophora*).—San Domingo.
fortipes WALKER, see *Pecckia*.
fulvipes MACQUART, Dipt. Exot., II, 3, 105, pl. XII, f. 5.—Cuba.
fulvipes (bis) WALKER, Dipt. Saund., 328.—U. S.
 St. Augustine, Fla.—Johnson.
fuscianalis VAN DER WULP, Biologia, Dipt., II, 275.—Vera Cruz and Tabasco, Mex.
georgina WIEDEMANN, Auss. Z. II, 357.—Ga.
 HARRIS, Ins. Inj. Veget., 3d edit., 613, oc. in Mass.
 WALKER, List, IV, 829, oc. in Brit. Amer.
 BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., V, 414, note.
helicis TOWNSEND, Psyche, Feb., 1892, 220.—Ohio; bred from *Helix thyrodes*.
 COQUILLETT, Proc. Acad. Nat. Sci. Phil., 1895, 317 (*Helicobia*); Proc. U. S. N. M., XXII, 255, oc. in Porto Rico (id.).—Fla., Miss., Ill., Ohio, D. C., Cal.
 HOWARD, Ins. Life, VI, 372, records breeding from *Loxosteges sticticalis*.
 TOWNSEND, Psyche, June, 1893, 468, reared from *Lachnostenus* sp., *Picris rapae*, and *Leucania unipuncta* by Forbes.
 MORGAN, Bull. 30, n. ser., Div. of Ent., 1901, 25, bred from *Melanoplus differentialis*.—Miss.
 N. J.—Smith Cat.; White Mts., N. H.—Slosson.
hunteri HOUGH, Kans. Univ. Quart., VII, 207–210, figs.; also in Hunter's "Alfalfa, Grasshoppers and Bees," Bull. Ent. Dept., Univ. of Kans., 34, fig.—Kansas; bred from *Melanoplus differentialis*.
 MORGAN, Bull. 30, n. ser., Div. of Ent., 1901, 25, bred from *Melanoplus differentialis*.—Miss.
immanis WALKER, see *Pecckia*.
importuna WALKER, List, IV, 819.—"N. A.?"
incerta WALKER, Dipt. Saund., 324.—Jamaica.
 HOWARD, Canad. Ent., XXXIII, 43, oc. Va., bred from cowdung.
 Jamaica—Johnson; Cuba—Bigot, in Sagra.
innota WALKER, Trans. Ent. Soc., n. ser., V, 308.—Mex.
intermutans WALKER, see *Pecckia plumipes*.
lambens WIEDEMANN, Auss. Z. II, 365.—W. I.
 HOWARD, Proc. Wash. Acad. Sci., II, 567, note on habits.
 Porto Rico—Roeder and Coquillett.
lanipes DESVOIDY, Myodaires, 336.—Carolina.
leucaniæ TOWNSEND, Psyche, June, 1893, 468.—Ill.; bred from *Leucania unipuncta* How.
l'herminieri DESVOIDY, Myodaires, 339 (*Myophora*).—Carolina.
micropyga VAN DER WULP, Biologia, Dipt., II, 279.—Guerrero, Mex.
micropygialis WILLISTON, Trans. Ent. Soc. Lond., 1896, 363.—St. Vincent, W. I.
muscoides BIGOT, in Sagra's Cuba, 816.—Cuba.
oberrans VAN DER WULP, Biologia, Dipt., II, 283.—Guerrero, Mex.
obsolete WIEDEMANN, Auss. Zweifl., II, 367.—W. I.
 ? GIGLIO-TOS, Ditt. del Mess., III, 68, doubtful oc. in Tuxpan, Mex.
occidua FABRICIUS, Syst. Ent., IV, 315; Syst. Antl., 288 (both *Musca*).—W. I.
 WIEDEMANN, Auss. Zweifl., II, 368.—W. I.
 COQUILLETT, Proc. U. S. N. M., XXII, 254, oc. in Porto Rico.
ochripyga VAN DER WULP, Biologia, Dipt., II, 285.—Guerrero, Tabasco and N. Yucatan, Mex.

- opifera** COQUILLETT, Insect Life, v. 22.—Los Angeles, Cal.: parasitic on *Melanoplus devastator* Scud.
- otiosa** WILLISTON, Trans. Ent. Soc. Lond., 1890, 364.—St. Vincent, W. I.
- pallinervis** THOMSON, Eugenies Resa, 535.—California and Honolulu.
- pallipes** WALKER, Dipt. Saund., 329.—U. S.
- pavida** WILLISTON, Trans. Ent. Soc. Lond., 1890, 365.—St. Vincent, W. I.
- pernetta** WALKER, Trans. Ent. Soc., n. ser., v. 308.—Mexico.
- pexata** VAN DER WULP, Biologia, Dipt., II, 284.—Guerrero, Vera Cruz and Tabasco, Mex.
- plinthopyga** WIEDEMANN, Auss. Zweifl., II, 360.—St. Thomas, W. I.
- WALKER, Linn. Trans., XVII, 352, oe. in Brazil.
- GIGLIO-TOS, Ditt. del Mess., III, 69.—Orizaba and Tuxpango, Mex.
- Porto Rico—Roeder and Coquillett; Jamaica—Johnson.
- plumigera** VAN DER WULP, Biologia, Dipt., II, 273, pl. VII, f. 6.—Tabasco, Mex.
- plumipes** DESVOÏDY, see *Pecchia*.
- prævolans** VAN DER WULP, Biologia, Dipt., II, 275, pl. VII, f. 8.—Guerrero and Orizaba, Mex.
- protrita** WALKER, Trans. Ent. Soc., n. ser., v. 317 (*Inthomyia*).—Mexico.
- The type is a female *Sarcophaga*—STEIN, 205.
- pusilla** BIGOT, in Sagra's Cuba, 817.—Cuba.
- pusiola** VAN DER WULP, Biologia, Dipt., II, 278.—Mexico City, Guerrero and Orizaba, Mex.
- quadrisetosa** COQUILLETT, Ent. News, XII, 17 (*Helicobia*).—Md., D. C., Va.
- HOWARD, Proc. Wash. Acad. Sci., II, 508 (id.), note on habits; breeds in human excrement; Canad. Ent., XXXIII (id.), oe. in Va., bred from cow-dung.
- querula** WALKER, List, IV, 821.—"N. A.?"
- rabida** WALKER, List, IV, 823.—Nova Scotia.
- rapax** WALKER, List, IV, 818.—"N. A.?"
- rediviva** WALKER, List, IV, 823.—Martin Falls, Canada.
- rubella** WIEDEMANN, Auss. Zweifl., II, 357.—Antigua.
- rufipalpis** MACQUART, Dipt. Exot., II, 3, 102.—Brazil.
- VAN DER WULP, Notes from the Leyden Museum, IV, 88; Tijdschr. v. Ent., XXVI, sep. 36, oe. in Curaçao and note.
- rufitibia** VAN DER WULP, Biologia, Dipt., II, 270, pl. VII, f. 3.—Guerrero, Mex.
- rufiventris** WIEDEMANN, Auss. Zweifl., II, 362.—Brazil.
- BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., V, 414, notes; occurs in Texas.
- sarraceniæ** RILEY, Trans. Acad. Sci. St. Louis, III, 238; App. to 4th Rept. U. S. Ent. Comm., quotes orig. desc. of larva and pupa.—Mo.
- RILEY, 2d Rept. U. S. Ent. Comm., 262; Gen. Index Mo. Repts., 60.
- COMSTOCK, Rept. Dept. Agr., 1881, 304, pl. XIV, f. 2, reared from pupa of *Aletia argillacea* in the south.
- HOWARD, Proc. Wash. Acad. Sci., II, 565, figs. and life hist.; bred from human excrement.
- MORGAN, Bull. 30, n. ser., Div. Ent., 1901, 25, figs. larva and adult; bred from *Melanoplus differentialis*.—Miss.
- Fla.—Johnson; White Mts., N. H.—Slosson; Axton, N. Y.—M. and H. Province of Quebec—Fyles.
- setulosa** VAN DER WULP, Biologia, Dipt., II, 276.—Durango, Mex.
- ? **spinigena** RONDANI, Arch. Zool., III, 26.—Valdivia, S. A.
- GIGLIO-TOS, Ditt. del Mess., III, 68, note.—Mexico.
- VAN DER WULP, Biologia, Dipt., II, 287, note; doubts the generic ref.

- stellata** VAN DER WULP, Biologia, Dipt., II, 272.—Guerrero, Vera Cruz and Tabasco, Mexico.
- stimulans** WALKER, List, IV, 817.—“N. A.?”
- sueta** VAN DER WULP, Biologia, Dipt., II, 281.—Guerrero, Mex.
- surrubea** VAN DER WULP, Biologia, Dipt., II, 273.—Tabasco, Mex.
- taitensis** SCHINER, Novara, 314.—Tahiti.
- VAN DER WULP, Tijdschr. v. Ent., xxvi, sep. 36, oc. in Guadeloupe and note.
- tenuiventris** VAN DER WULP, Biologia, Dipt., II, 282.—Guerrero and Tabasco, Mex.
- tridens** VAN DER WULP, Biologia, Dipt., II, 281.—Guerrero, Mex.
- trigonomaclata** MACQUART, Dipt. Exot., II, 3, 106, pl. XII, f. 2.—Mex.
- tripartita** VAN DER WULP, Biologia, Dipt., II, 284.—Jalisco, Mex.
- triplasia** VAN DER WULP, Biologia, Dipt., II, 283, pl. VII, f. 10.—Guerrero, Mex.
- trivialis** VAN DER WULP, Biologia, Dipt., II, 277.—Mexico, numerous places.
- HOWARD, Proc. Wash. Acad. Sci., II, 567, oc. in Md., D. C. and Va.; bred from human excrement.
- trivittata** MACQUART, Dipt. Exot., II, 3, 105, pl. XII, f. 3.—Cuba, Mex.
- BIGOT, Sagra's Cuba, 816.—Cuba.
- turbata** VAN DER WULP, Biologia, Dipt., II, 276.—Guerrero, Tabasco and Orizaba, Mex.
- uncata** VAN DER WULP, Biologia, Dipt., II, 277.—Guerrero and N. Yucatan, Mex.
- vagabunda** VAN DER WULP, Biologia, Dipt., II, 270, pl. VII, f. 4.—Guerrero, etc., in Mexico.
- ventricosa** VAN DER WULP, Biologia, Dipt., II, 274.—Guerrero and Tabasco, Mex.
- vigil** WALKER, List, IV, 831.—Nova Scotia.
- villipes** VAN DER WULP, Biologia, Dipt., II, 269, pl. VII, f. 2.—N. Sonora and Guerrero, Mex.
- viridescens** DESVOUDY, Myodaires, 342 (*Myophora*).—Nova Scotia.
- volucris** VAN DER WULP, Biologia, Dipt., II, 285.—Guerrero, Mex.
- xanthopyga** VAN DER WULP, Biologia, Dipt., II, 271.—Guerrero, Morelos and Orizaba, Mex.
- Note*.—Brauer and Bergenstamm, in Zweifl. d. Kaiserl. Mus., V, 414, record “*Sarcophaga xanthophyga* S.” from South Carolina. I presume this refers to *S. xanthophora* SCHINER, Novara, 313, from South America.

SARCODEXIA.

TOWNSEND, Jour. Inst. of Jamaica, I, 105, 1892.

BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., VI, 193, “from the description a *Sarcophaga*.”

sternodontis TOWNSEND, op. cit.—Kingston, Jamaica; bred from a Cerambycid. In the same Journal for Dec., 1892, it is recorded as bred from the scorpion *Centrurus edwardsii*.

SARCOPHAGULA.

VAN DER WULP, Tijdschr. v. Ent., XXX, 173, 1887; Biologia, Dipt., II, 289, 1890, def. and table of Mexican species.

canuta VAN DER WULP, Biologia, Dipt., II, 289, pl. VII, f. 12.—Guerrero, etc., in Mexico.

imbecilla VAN DER WULP, Biologia, Dipt., II, 289.—Guerrero, etc., in Mexico.

tenuis VAN DER WULP, Biologia, Dipt., II, 290.—Guerrero, etc., in Mexico.

ERYTHRANDRA.

BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., v. 368, 1891; vi. 165, 1893.

picipes BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., v. 368; vi. 165.—Ga.

SARCOPHILODES.

BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., iv. 164, 1883; vi. 166, 1893.

puella WILLISTON, Trans. Ent. Soc. Lond., 1896, 361, pl. xii, f. 120 bis.—St. Vincent, W. I.

pusilla WIEDEMANN, Auss. Zweifl., II, 337 (*Tachina*).—W. I.

BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., iv. 164; v. 369; vi. 166, gen. ref. from type.

? **rufocaudata** BIGOT, Annales, 1888, 269 (*Megarlea*).—Mex.

COQUILLETT, Jour. N. Y. Ent. Soc., VII, 1890, 218, gen. ref., with a doubt.

BRAUER, Sitzungsbericht d. K. Akad., cviii, 22, would locate in a new genus near *Tephromyia*, from type.

SAROTHROMYIA.

BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., v. 365, 1891; vi. 166, 1893, place near *Brachycoma*.

femoralis SCHINER, Novara, 315 (*Sarcophila*).—Brazil.

Lake Worth, Fla.—Johnson, with gen. ref.

JOHNSONIA.

COQUILLETT, Proc. Acad. Nat. Sci. Phil., 1895, 316.

elegans COQUILLETT, loc. cit.—St. Augustine, Fla.

MUSCIDÆ.

BIGOT, Bull. Soc. Zool. France, 1887, 586, table of all genera.

TOWNSEND, Trans. Amer. Ent. Soc., xix, 1892, table of genera.

GIRSCHNER, Berl. Ent. Zeitsch., xxxviii, 297, 312, 1893, new system of the family: Ent. Nachrichten, xxi, 82–86, 1895; Ill. Woch. f. Ent., I, 12–16, and in a few following numbers, 1896.

VAN DER WULP, Biologia, Dipt., II, 291, 1896, table of Mexican genera.

BRAUER, Sitzungsbericht d. K. Akad., cviii, 495, 1899, table of genera of Caliphorinæ. In the same paper he remarks that some of Bigot's supposedly North American specimens belong to genera hitherto confined to the eastern hemisphere, "so that I must assume that the locality assigned to many of the species in the Bigot collection is erroneous."

HOUGH, Proc. Acad. Nat. Sci. Phil., 1898, 165–172, gives a valuable article on the anatomy of Muscidæ; in Ent. News, x, 62–66, 1899, he discusses the classification of the family; see also his article in Biol. Bull., I, 21, 1899.

TYREOMMA.

VAN DER WULP, Biologia, Dipt., II, 292, 1896.

BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., v. 381, 1891, described as Wulp's genus, from his MS. name on the specimens; vi. 135, 1893, full desc.

muscinum VAN DER WULP, Biologia, Dipt., II, 293, pl. vii, f. 13.—Guerrero, Mex.

POLLENIA.

- DESOVIDY, Myodaires, 412, 1830.
 SCHINER, Fauna Austr., 1, 585, 1862.
 BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., IV, 155, 1899; VI, 179, 1893.
 HOUGH, Ent. News, X, 63, 1899; Zool. Bull., II, 283, 1899, figs. chætotaxy.
glabricula BIGOT, Bull. Soc. Zool. France, 1887, 594 (*Nitellia*).—Cal.
 BRAUER, Sitzungsbericht d. K. Akad., CVIII, 521, gen. ref. from type.
obscura BIGOT, Bull. Soc. Zool. France, 1887, 597.—N. A.
 HOUGH, Zool. Bull., II, 283, says the desc. is unrecognizable.
 BRAUER, Sitzungsbericht d. K. Akad., CVIII, 517, gen. ref. confirmed from type.
rudis FABRICIUS, Ent. Syst., IV, 314 (*Musca*); 315 (*M. obscura*); Syst. Antl., 287 (*Musca*).—Europe.
 FALLÉN, Muscides, 48 (*Musca*).
 MEIGEN, Syst. Beschr., V, 66, 67 (*Musca rudis, varia, and depressa*). [Hgh.]
 SCHINER, Fauna Austr., I, 586.
 DALL, Proc. U. S. N. M., 1883, 635, habits, notes by Riley.—Geneva, N. Y.
 LINTNER, 4th N. Y. Rept., 309–314: the Cluster Fly, sometimes gathers in houses in immense numbers in the cooler season.—N. Y.
 RILEY and HOWARD, Insect Life, V, 263, notes from correspondence on clustering in houses.
 HOUGH, Zool. Bull., II, 283, syn.
 HOWARD, Canad. Ent., XXXIII, 44, oc. in Va.: bred from cowdung.
 Quebec—Wulp; N. J.—Smith Cat.; Montreal—Chagnon; Ohio—Webster.
vespillo FABRICIUS, Ent. Syst., IV, 318 (*Musca*); Syst. Antl., 292 (id.).—Europe.
 MEIGEN, Syst. Beschr., V, 65 (id.).
 WALKER, List, IV, 907, oc. in Nova Scotia.
 SCHINER, Fauna Austr., I, 586.
 HOUGH, Biol. Bull., II, 283, fig. 1, confirms oc. in N. A.

CHRYSMYIA.

- DESOVIDY, Myodaires, 444, 1830.
 BRAUER and BERGENSTAMM, Zweifl. d. Kaiserl. Mus., V, 391, 1891 (*Paralucilia* in part).
 GIGLIO-TOS, Ditt. del Mess., IV, 5, 1895, def.
 HOUGH, Ent. News, X, 64, 1899, def., and includes the species formerly called *Compsomyia*.
aztequina BIGOT, Annales, 1877, 252.—Mex.
 GIGLIO-TOS, Ditt. del Mess., IV, 5, makes a syn. of *macellaria*.
 BRAUER, Sitzungsbericht d. K. Akad., CVIII, 523, confirms gen. ref. from type.
cærulescens DESVOUDY, Myodaires, 447, 8.—Carolina.
callipes BIGOT, Annales, 1877, 249 (*Somomyia*).—Mex.
 BRAUER, Sitzungsbericht d. K. Akad., CVIII, 524, gen. ref. (*Compsomyia*).
certina WALKER, List, IV, 873 (*Musca*).—Fla.
 Probably same as *Pseudopyrellia cornicina*.
decora DESVOUDY, Myodaires, 448.—W. I.
flavigena BIGOT, Annales, 1877, 249 (*Somomyia*).—Mex.
 BRAUER, Sitzungsbericht d. K. Akad., CVIII, 522, refers the type to *Compsomyia*.

fulvipes MACQUART, see *macellaria*.

? **hyacinthina** DESVOIDY, Myodaires, 450.—S. A.

MACQUART, Dipt. Exot., II, 3, 148.—N. A. Very doubtful—J. M. A.

HOUGH, Kans. Univ. Quart., IX, 204, syn., etc., under the name of *segmentaria* FABR.; as it is scarcely a North American species, I do not rectify the nomenclature.

l'herminieri DESVOIDY, Myodaires, 446.—Carolina.

macellaria FABRICIUS, Syst. Ent., 776 (*Musca*); Ent. Syst., IV, 319 (id.); Syst. Antl., 292 (id.).—W. I.

 MACQUART, Hist. Nat. Dipt., II, 244.
 RONDANI, Dipt. Ital. Prod., V, 230 (*Lyperosia*).
 WILLISTON, Entom. Americana, V, 180 (*cornicola*).—Va.
 LINTNER, Country Gentleman, Sept. 20, 1888, an unknown fly occurring on horns of cattle; Oct. 11, specimens received and sent to Osten Sacken; Nov. 29, determined as *H. serrata*, on authority of Kowarz.
 LINTNER, 5th N. Y. Rept., 1889, 220-227, bibliog., habits, figs.; “The Horn Fly.”—N. Y.
 RILEY and HOWARD, Ins. Life, II, 60 (*cornicola*); 93, full biology, syn., etc.
Note.—It appears from the article just mentioned that this European species was first observed in New Jersey and Maryland, on cattle, in the summer and fall of 1887, although the first reference in print was by Lintner, supra, in 1888. Williston saw it from Pennsylvania in 1887 also. The subsequent spread of the fly was traced by frequent references in Insect Life, in the second and following volumes; the references may be found in the general index of the periodical. Other references which I have collected are mostly to brief notes; the principal ones I list.
 WILLISTON, Amer. Nat., 1889, sep., 7 pp. and pl.
 SMITH, Bull. 62, N. J. Expt. Sta.; Psyche, V, 343, figs., 1890.
 LUGGER, 2d Rept. Ent. Minn., 1896, 162-166, pl. XII, f. 136.
 RILEY, Dept. Agr. Rept., 1889, 345-348, pl. IV, V; life hist., etc.; 1891, 239, notes on spread; 1892, 159, same.
 FLETCHER, Bull. 14, Cent. Exp. Farm, Ottawa, Canada; Trans. Royal Soc. Canada, Sec. ser., V, 229, notes decrease.
 HERRICK, Bull. 53, Miss. Ex. Sta., 1900.
 WASHEURN, Bull. 77, Minn. Ex. Sta., 31, fig.

HOUGH, Biol. Bull., I, 22, figs.; comparison with *alcis*.

Generally distributed throughout the United States and Eastern Canada; it reached Idaho in 1901; the larvae are found in fresh cow-dung.

HEMICHLORA.

VAN DER WULP, Biologia, Dipt., II, 303, 1896.

vittigera BIGOT, Bull. Soc. Zool. France, 1887, 613 (*Cyrtoneura*).—Mexico.

VAN DER WULP, Biologia, Dipt., II, 339, 1896 (*Phorbia* and *Chortophila*).

MEADE, Desc. List, 43 and 47, 1897 (*Phorbia* and *Chortophila*).

TOWNSEND, Trans. Amer. Ent. Soc., XIX, 293, 1892, notes.

Note.—Van der Wulp, and Meade following him, make a distinction between *Phorbia* and *Chortophila* in that the former has the abdomen narrow and depressed and in the latter it is cylindrical. Stein, however, in Berl. Ent. Zeitsch., XLII, 231, recognizes the equivalence of the two names, although adopting *Chortophila*, the later.

acra WALKER, of Mrs. Slosson's White Mt. list, is an error; see *Homalomyia manicata*.

alaba WALKER, List, IV, 948 (*Anthomyia*).—N. A.

STEIN, Die Walk. Anth., 186, pt. desc. of type (*Chortophila*).

WILLISTONIELLA.

- MIK, Wien. Ent. Zeit., XIV, 136, change of name.
 WILLISTON, Psyche, 1895, 184 (*Rhopalomyia*, preoc.).
 The genus is reported from North America by Williston, Ent. News, VII, 185. The described species are South American.

TRYPETIDÆ.

- LOEW, Mon. N. A. Dipt., III, 327, 1873, table of genera.
 COQUILLETT, Jour. N. Y. Ent. Soc., VII, 267, 1899, table of genera.

Note.—The order followed is essentially that of the table in Williston's Manual, although Coquillett has pointed out some seeming defects in the relation of genera therein. The genera of this family are closely interwoven, and mostly based on plastic characters; hence a slight difference in the emphasis placed on one set of characters has the effect of throwing a large number of species into other genera than they previously occupied. This change of emphasis Mr. Coquillett seems to have adopted, as compared with Loew, who established most of the genera; but as he has not published anything to justify his new generic references in most cases, I have been slow to accept them. The synonymy of species by Mr. Coquillett in Jour. N. Y. Ent. Soc., VII, 259–268, seems to me to do a great injustice to Mr. Doane, whose species were very carefully and accurately worked out. From an examination of Doane's material, I am satisfied that Coquillett was wrong in all, or nearly all, of the assertions he made regarding the synonymy of Doane's species; this was shown in a rejoinder published by Doane, op. cit., VIII, 47.

TOXOTRYPANA.

- GERSTÆCKER, Stett. Ent. Zeit., XXI, 191, 1860.

ANASTREPHA.

SCHINER, Novara, 263, 1868.

LOEW, Mon. N. A. Dipt., III, 227, 1873 (*Acrotoxa*).

OSTEN SACKEN, Cat., 260, 1878, makes the *Leptoxyda* of Macquart, Dipt.

Exot., II, 452, 1835, the same as this; it was amended by Macquart, Dipt. Exot., Suppl., II, 2, 216, 1841, to *Leptoxys*, which is apparently preoccupied. This raises a peculiar question of nomenclature. Coquillett, Jour. N. Y. Ent. Soc., VII, 259, 1899, asserts that *Leptoxys* is not the same genus. I deem it safest to make no change under these con-

- ditions. The same question, with the synonymy of *Acrotoxa*, is discussed by Van der Wulp, Biologia, Dipt., II, 404, 1899.
- acidusa** WALKER, List, IV, 1014 (*Trypeta*).—Jamaica.

SCHINER, Fauna Austr., ii, 125, 1864.

baccharis COQUILLET, Canad. Ent., xxvi, 73.—Cal.; larvæ in galls on *Baccharis*.

cerasi Fauna Suec., 2d ed., p. 461, 1761 (*Musca*).—Europe.

Note.—Hagen, Canad. Ent., xv, 159, records finding in cherries at Cambridge Mass., the larvae of this European species, which is referred by Schiner to *Rhagoletis* (Fauna Austr., II, 121). As nothing further has been brought to light, it is very likely that the species found by Hagen was the native *Rhagoletis cingulata*, q. v.

flaveola COQUILLET, Dipt. of Commander Ids., 345.—Bering Id.

DROSOPHILA.

FALLÉN, Geomyzides, 4, 1823.

MEIGEN, Syst. Beschr., VI, 81, 1830.

SCHINER, Fauna Austr., II, 275, 1864.

WILLISTON, Trans. Ent. Soc. Lond., 1896, 406, table of 23 St. Vincent species.

Note.—The genus *Scaptomyza* (HARDY, Proc. Berwickshire Nat. Club, 349, 1849) is accepted by Mr. Coquillett; it would include a considerable number of the species of *Drosophila*. See Schiner, Fauna Austr., II, 276, and Coquillett, Proc. Wash. Acad. Sci., II, 462.

Note 2.—The apple burrowing habit attributed to *Drosophila* sp. in Amer. Nat., II, 641, does not seem to be sufficiently corroborated. More likely the actual burrower was *Trypetta pomonella*, and *Drosophila* lived in the cavities.

adusta LOEW, Cent., II, 98.—D. C. N. J.—Smith Cat.

SPEISER, Zeitsch. f. Hym. u. Dipt., 1902, 171, type redesc. (the real type may be the female of Townsend's *antrozoi*, given above).

APPENDIX.

Literature of North American Diptera for the year 1904, with enumeration of new species, genera, etc.

Adams, C. F.

Notes and Descriptions of New North American Diptera. *Kans. Univ. Sci. Bull.*, II, 433-455; June, 1904.

New: *Simulium notatum*, *Mydas abdominalis*, *Xylophagus nitidus*, *Chrysopila lucifera*, *bella* and *flavibarbis*, *Symphoromyia flavipalpis*, *Leptis pleuralis* and *palpalis*, *Psilocephala occipitalis* and *lateralis*, *Thereva anomala*, *Scenopinus mirabilis* and *electa*, *Nausigaster scutellaris*, *Sphyximorpha snowi*, *Conops gracilis*, *Tetanocera inopa*, *Ictericia fasciata*, *Urellia flavula*, *concreta* and *occidentalis*, *Elachiptera bilineata*, *Hippelates splendens*, *Limosina exigua*, *occidentalis* and *sordipes*.

Tables of Species: *Xylophagus*, *Chrysopila*, *Leptis*, *Ictericia*, *Urellia* and *Limosina*.

On the North American Species of Siphonella. *Psyche*, XI, 103, 104; Oct., 1904.

New: *S. parva* and *nigra*.

European species from this realm: *S. trilinata* MEIG.

Descriptions of New Oscinidae. *Ent. News*, XV, 303, 304; Nov., 1904.

New: *Chlorops pulla*, *lasciva*, *rubrivittata*, *annulata* and *certima*.

Aldrich, J. M.

New Species of Phoridae in Brues's Monograph. *Trans. Amer. Ent. Soc.*, XXIX, 331-400. Pub. Jan., 1904. Four species, included in the body of the Catalogue.

The Genus *Psilopus* of Authors. *Canad. Ent.*, XXXVI, 246, 247; Aug., 1904.

Bibliography and synonymy of *Psilopodinus* and *Agonosoma*; no new species.

A Contribution to the Study of North American Dolichopodidae. *Trans. Amer. Ent. Soc.*, XXX, 269-286; 1904.

New: *Pelastoneurus scutatus*, *parvus*, *falcatus* and *proximus*, *Paracanthus vicinus*, *Psilopodinus pilicornis*, *crinitus*, *viridicoxa* and *flavipes*, *Agonosoma rotundiceps* and *costale*; also two Brazilian species. Table of genera and tables of species in several genera.

Back, E. A.

New Species of North American Asilidae. *Canad. Ent.*, XXXVI, 289-293; Oct., 1904.

New: *Dasyllis cinerea* and *fernaldi*, *Saropogon rufus* and *albifrons*, *Osphriocerus albifasciatus*, *Anisopogon johnsoni*.

Baker, C. F.

Invertebrata Pacifica, I, 17-40; Feb. 10, 1904. Printed by the Author, Claremont, Cal.

A long faunal list of Diptera from California and Nevada. The new species are described by Coquillett, q. v. The following European are new to North America: *Lonchoptera lacustris* MEIG., *Psilopa compta* MEIG., *Mosillus cencus* FALL.

Note.—The *Limnophora borealis* STEIN is a clerical error; there is no such species—Coquillett in litt.

Banks, Nathan.

The "Yellow Fly" of the Dismal Swamp. Ent. News, xv, 290, 291; Nov., 1904.

Identified as *Diachlorus ferrugatus* FABR.

Bezzi, Marie.

Verzeichniss der bis jetzt bekannten Arten der Dipteren-Gattung *Drapetis* Meig. Wien. Ent. Zeit., xxiii, 143-146, 1904.

Includes the North American species; none new.

Brimley, C. S. and Sherman, Franklin.

List of the Tabanidae of North Carolina. Ent. News, xv, 270-275.

No new species.

Brues, C. T.

Monograph of N. A. Phoridae. This is included in the body of the Catalogue; see the family, p. 334.

Notes on Trichobius and the Systematic Position of the Streblidae. Bull. Amer. Mus. Nat. Hist., xx, Art. viii.

No new species.

Card, F. W. and Stene, A. E.

Article on the Apple Maggot (*Rhagoletis pomonella*) in 17th Rept. of R. I. Expt. Station, 1904, 191-201. Purely economic.

Chagnon, G.

Additions to the Syrphidae of the Province of Quebec. 34th Ann. Rept. Ent. Soc. of Ontario, 1904, 48, 49.

Eight species mentioned; none new.

Chittenden, F. H.

The Cherry Fruit Fly. Bulletin No. 44, Div. of Ent., 70-75, 1904.

Review of the habits, etc., of *Rhagoletis cingulata* Lw.

Cockerell, T. D. A.

Three New Cecidomyiid Flies. Canad. Ent., xxxvi, 155, 156; June, 1904.

New: *Diplosis coloradella*, *Rhabdophaga porterae*, *Cecidomyia perocculata*.

Cook, Melville T.

Galls and the Insects Producing Them. Ohio Naturalist, 1904.

A series of articles from a botanical standpoint chiefly; several Dipterous galls described; no new species.

Coquillett, D. W.

Several New Diptera from North America. Canad. Ent., xxxvi, 10-12; Jan., 1904.

New: *Culex duprezi*, *Janthinosoma (Conchyliastes) varipes*, *Metriocnemus knabi*, *Cuterebra grisca*, *Bischofia varia* (the last a genus of Scionyzidae heretofore known from Europe).

Notes on *Culex nigrithulus*. Ent. News, xv, 73, 74; Feb., 1904.

The American species formerly called *nigrithulus* is distinct, and the name *salinarius* is proposed for it. *Nigrithulus* is not North American.

Invertebrata Pacifica. Reports on the Californian and Nevadan Diptera, 1

(See notice under C. F. Baker.) Mr. Coquillett described the new species as follows: *Mycetophila trifasciata* and *fencestrata*, *Neocnephelia pullata*, *Sciophila calcarata*, *Dilophus occipitalis*, *Leptis flavonigra*, *Phenecus opacus*, *Tabanus opacus*, *Thereva flavicanda*, *Acrocera bakeri*, *Rhamphomyia curvipes*, *Chilosia plumosa*, *Zagonia* (n. gen. Geomyzidae) *flava*, *Hippelates microcentrus*, *Chyliza robusta*, *Melicria occidentalis*, *Spilog-*

grapha inaequalis, *Tephritis palpalis*, *Euaresta adspersa*, *Sapromyzæ cæsia* and *univittata*, *Eccoptomera* (Europ. gen. *Helomyzidæ*) *simplex*, *Cænosia argentata* and *majuscula*, *Lispa polita*, *Phaonia fimbriata*, *Admontia setigera*, *Biomyia mutabilis*, *Scleropogon jubatus*, *Leptomydas hirtus* and *concinus*.

Diptera from Southern Texas, with Descriptions of New Species. Jour. N. Y. Ent. Soc., xii, 31-35; March, 1904.

Eight described species listed; the following new: *Cyphomyia schæfferi*, *Phthiria unimaculata*, *Holopogon latus*, *Stenopogon tenebrosus*, *pumilus* and *nitens*, *Erae tuberculata*, *Anastrepha pallens*, *Scpsis pleuralis*.

New Diptera from Central America. Proc. Ent. Soc. Wash., vi, 90-98; May, 1904.

New: *Ceratopogon terminalis*, *Sciara trifasciata*, *Dilophus fumesus* and *rhynchosps*, *Psilocephala pruinosa*, *Conops pallifrons*, *Paradidyma orbitalis*, *Hypostena gracilis*, *Chætoclusia* (n. gen. *Heteroneuridæ*) *bakeri*, *Sapromyza varia*, *albipes* and *triseriata*, *Euxesta juncta* and *fenestrata*, *Ictericia apicalis*, *Notiphila frontalis*, *Scutops* (n. gen. *Geomyzidæ*) *fascipennis*, *Chlorops capillata*.

New North American Diptera. Proc. Ent. Soc. Wash., vi, 160-192; July, 1904.

New: *Ceratopogen medius*, *Tæniorhynchus nigricans* and *signipennis*, *Culex nivitarsis* and *pullatus*, *Eugnoriste brevirostris*, *Acnemia varipennis*, *Phronia tenebrosa*, *Calosia* (Europ. gen. *Mycetophilidæ*) *pygophora*, *Platyura pullata*, *Bibiodes* (n. gen. *Bibionidæ*) *halteralis*, *Symphoromyia securifera*, *Phthiria melanoscuta*, *fulvida*, *marginata*, *vittiventris*, *nubeculosa*, *inornata*, *badia*, *picturata*, *flaveola*, *amplicella* and *bicolor*, *Aeroctrichus atratus*, *Psilocephala aurantiaca*, *Leptogaster virgatus* and *hirtipes*, *Ablautus flavipes* and *rubens*, *Stenopogon nigrutilus*, *Laphystia flavipes*, *limatula* and *opaca*, *Diocrodes* (n. gen. *Asilidæ*) *flavipes*, *Metapogon* (n. gen. *Asilidæ*) *giltipes* and *punctipennis*, *Cyrtopogon nigricolor*, *tibialis*, *maculosus* and *varipennis*, *Saropogon luteus*, *hyalinus* and *semiustus*, *Psilopodinus* (*Sciapus*) *pruinosus*, *Distichona auriceps*, *Sarcophaga amblycorypha*, *Pegomyia bucculenta*, *Nerius longicornis*, *Lauxania signatifrons*, *Sapromyza picticornis*, *Drosophila ordinaria*, *Sinophthalmus* (n. gen. *Geomyzidæ*) *pictus*, *Agromyza tæniola*.

The Genera of the Dipterous Family Empididæ (addenda). Proc. Ent. Soc. Wash., vi, 51.

No new species.

Notes on the Syrphid Fly *Pipiza radicum* Walsh and Riley. Proc. Ent. Soc. Wash., vi, 200.

Czerny, P. Leander.

Revision der Helomyziden. I. Wien. Ent. Zeit., xxiii, 199-244, 1904. II. Op. cit., 263-286, 1 pl.; Dec. 31, 1904.

Quotes descriptions of North American species; records *Helomyza nemorum* Meig., a European species, from Colorado. The work is still incomplete.

Dyar, H. G.

The Life History of *Culex cantans* Meig. Jour. N. Y. Ent. Soc., xii, 36-38, 1904.

The Life History of *Culex varipalpus* Coq. Jour. N. Y. Ent. Soc., xii, 90-99, 1904.

Larva of *Culex punctor* Kirby, with Notes on an Allied Form. Jour. N. Y. Ent. Soc., XII, 169-171, 1904.

New: *Culex trichurus*.

Brief Notes on Mosquito Larvae. Jour. N. Y. Ent. Soc., XII, 172-174, 1904.
No new species.

Notes on the Mosquitoes of British Columbia. Proc. Ent. Soc. Wash., VI, 37-41, 1904.
Notes on biology of 17 species; none new.

Dyar, H. G. and Knab, Frederick.

Diverse Mosquito Larvae that produce Similar Adults. Proc. Ent. Soc. Wash., VI, 143, 144, 1904.
No new species.

Emerton, J. H.

A Dipterous Parasite of the Box Turtle. Psyche, XI, 34; Apr., 1904.
Brief note on *Sarcophaga* sp.

Felt, E. P. and Young, D. B.

Importance of Isolated Rearings of Culicid Larvae. Science, XX, 312, 313; 1904.

New, briefly diagnosed: *Culex fitchii*, *lazarensis*, *cineraceoborealis*, *abserratus*.

Felt, E. P.

Mosquitoes or Culicidae of New York State. Bull. 79, N. Y. State Museum, Albany, 1904; pp. 241-409, 57 plates and many text figures.

New genera: *Culicada*, *Culicelsa*, *Ecculex*, *Culicella*, *Culiseta*, *Protoculex*.

New species: *Culicada onondagensis*, *Culiseta absobrinus* and *magnipennis*, *Corethra karncreensis* and *hintoni*, *Sayomyia rotundifolia* and *hudsoni*, *Culex abfitchii*.

Fletcher, Jas.

Notes of Captures. Diptera. 34th Ann. Rept. Ent. Soc. Ontario, 1904, pp. 68, 99.

Fifty-five species listed from Canada, none new.

French, G. H.

Gastrophilus epilepsalis Larvae and Epilepsy. Canad. Ent., XXXVI, 83, 84; March, 1904.

Reasserts his theory.

Girault, A. Arsène.

Tanypus dyari: Pupa and Adult Exclusion. Psyche, XI, 81, 82; Aug., 1904.

Grossbeck, John A.

Description of a new *Culex*. Canad. Ent., XXXVI, 332; Nov., 1904.
Culex siphonalis.

Descriptions of Two New Species of *Culex*. Ent. News, XV, 332, 333; Dec., 1904.

Culex pretans and *inconspicuus*.

Herrick, Glenn W.

Notes on the Life History of *Grabhamia jamaicensis*. Ent. News, XV, 81-84, 1 pl.; Mar., 1904.

Hine, Jas. S.

New Species of Tabanidae. Canad. Ent., XXXVI, 55, 56; Feb., 1904.

New: *Chrysops fulvistigma* and *brimleyi*.

On Diptera of the Family Ephydriidae. Ohio Naturalist, Feb., 1904.

New: *Psilopa fulvipennis*, *Cænia virida*.

European species identified from U. S.: *Cænia fumosa* STEN.

Tables of species of *Dichota* and *Cænia*.

The Diptera of British Columbia. Canad. Ent., xxxvi, 85-92; Apr., 1904.

Extensive list of described species.

New: *Euparyphus obliquus*, *Anthrax harveyi*.

European reported: *Pyrellia cæna* ZETT.

Insects Injurious to Stock in the Vicinity of the Gulf Biologic Station.

In Bull. No. 44, Div. of Ent., 57-60, 1904.

A few Tabanidæ mentioned; no new species.

Tabanidæ of the Western United States and Canada. Ohio Naturalist, v, 217-240; Dec., 1904.

Keys to genera and species. New species: *Chrysops coquilletti*, *Snow-icellus* (n. gen.) *atratus*, *Tabanus flavidus*, *laticeps*, *laticornis*, *osburni*, *productus*; some new synonymy.

Johnson, C. W.

Some Notes and Descriptions of Four New Diptera. Psyche, xi, 15-20; Feb., 1904.

New: *Tabanus whitneyi*, *Oncodes albiventris*, *Argyra aldrichi*, *Allophora magnapennis*.

Tabanus politus changed to *hinei*, on account of preoccupation.

Several important notes.

When to Collect Tabanidæ. Psyche, xi, 35; Apr., 1904.

List of species collected at Riverton, N. J.; some other notes; no new species.

Some of the Diptera to be collected during April and May. Psyche, xi, 37, 38; Apr., 1904.

General notes; no new species.

A Supplementary List of the Diptera of New Jersey. Ent. News, xv, 157-163; May, 1904.

Supplementary to the Smith Catalogue; no new species.

Knab, Frederick.

The Epistomal Appendages of Mosquito Laryæ. Jour. N. Y. Ent. Soc., xx, 175-177, 1904.

Mosquito Notes. Canad. Ent., xxxvi, 233-236; Aug., 1904.

New: *Grabhamia de-Niedmannii*.

Ludlow, C. S.

Anopheles of California, with Description of a New Species. Ent. News, xv, 9-14, 1 pl.; Jan., 1904.

New: *Anopheles franciscanus*.

McCracken, Isabel.

Notes on Stratiomyidæ. Canad. Ent., xxxvi, 14-24 and 53, 54; Jan. and Feb., 1904.

New: *Sargus teranus*. Several tables of species, and other matter.

Additional Notes on Nemotelus. Psyche, xi, 33, 34; Apr., 1904.

No new species.

Melander, A. L.

Notes on Stratiomyidæ. Canad. Ent., xxxvi, 14-24 and 53, 54; Jan. and Feb., 1904.

New: *Sargus teranus*. Several tables of species, and other matter.

Additional Notes on Nemotelus. Psyche, xi, 33, 34; Apr., 1904.

No new species.

Osburn, R. C.

The Diptera of British Columbia: The Syrphidæ. Canad. Ent., xxxvi, 213-

220 and 257-262; Aug. and Sept., 1904.

List of 78 species; none new.

Slingerland, M. V. and Johnson, Fred.

A New Grape Enemy; the Grape Blossom-Bud Gnat. Bull. 224, Cornell Expt. Station, p. 71; Nov., 1904.

An undetermined Cecidomyid; habits described.

Smith, John B.

Report on the Mosquito Investigation. Annual Report N. J. Expt. Station for 1903, published 1904, pp. 645-659.

No new species.

Notes on the Life History of *Culex dupreei* Coq. Ent. News, xv, 49-51, 1 pl.; Feb., 1904.

No new species.

Notes on Some Mosquito Larvae found in New Jersey. Ent. News, xv, 145-152, 1 pl.; May, 1904.

No new species.

The Common Mosquitoes of New Jersey. Bull. No. 171, N. J. Expt. Station, 1904; 40 pp., 12 plates and some text figures.

Valuable for biology; no new species.

Snodgrass, Robt. E.

The Terminal Abdominal Segments of Female Tipulidae. Jour. N. Y. Ent. Soc., xi, 177-188, 2 pl.; Dec., 1903.

The Hypopygium of the Tipulidae. Trans. Amer. Ent. Soc., xxx, 179-236, 11 pl.; Aug., 1904.

The Hypopygium of the Dolichopodidae. Proc. Cal. Acad. Sci., 3d ser., III, No. 10, pp. 273-288, 4 pl.; Sept., 1904.

The three preceding papers are purely anatomical, but not less valuable for classification, as a large number of genera are compared in each group.

Snow, F. H.

Lists of Coleoptera, Lepidoptera, Diptera and Hemiptera collected in Arizona by the Entomological Expeditions of the University of Kansas in 1902 and 1903. Kans. Univ. Sci. Bull., May, 1904, Vol. II. Diptera on pp. 341-346; 201 species, none new.

Speiser, P.

Typenuntersuchungen an Hippobosciden. Zeitsch. f. syst. Hym. und Dipterologie, iv, 82-89; March, 1904.

Type of *Olfersia sulcifrons* THOMSON is referred to *Pseudoloffersia*.

Zur Nomenklatur Blutsaugender Dipteren Amerikas. Insekten-Börse, 1904, 148, brief notice.

On account of preoccupation, *Simulium cinereum* BELLARDI is changed to *tephrodes*, and *Culicx affinis* ADAMS to *fetus*.

Stein, P.

Die Amerikanischen Anthomyiden des Königlichen Museums für Naturkunde zu Berlin und des Ungarischen National Museums zu Budapest. Annales Musei Nationalis Hungarici, II, 414-495, 1904.

Mostly South American. New from N. A.: *Aricia pulvillata*, *Trichopticus spiniger*, *Hylemyia spinilamellata* and *cænosiaformis*, *Cænosia compressa*.

European from N. A.: *Aricia serva* MEIG., *Spilogaster obscuripes* ZETT., *Spilogaster anceps* ZETT., *Homalomyia ornata* MEIG.

South American from N. A.: *Spilogaster gemina* WIED., *Limnophora serva* WIED.

Washburn, F. L.

Eighth Report of the State Entomologist of Minnesota, for the year 1903 (pub. Jan., 1904). 184 pp., with plates, etc.

Article on Hessian fly, pp. 1-11.

Ninth Report of the State Entomologist of Minnesota, for the year 1904 (pub. Dec., 1904). 107 pp., with col. plate, etc.

P. 185, notes on mostly undetermined Cecidomyid gall-makers on basswood, soft maple and box elder; p. 188, fumigation for *Diplosis violicola* Coq.

Webster, F. M.

Studies of the Habits and Development of *Neocarata rhodophaga* Coq. Bull. Ill. State Lab. Nat. Hist., VIII, 15-25, 1 col. pl.; Feb., 1904.

Wood, Clarence M.

Experiments in destroying Black Flies. Bull. 112, N. H. Expt. Station; May, 1904.

The species is *Simulium venustum* Say.

Weeks, Henry Clay.

First Anti-Mosquito Convention. Brooklyn, 1904, 84 pp.

Several general papers.

Bulletin No. 1, National Mosquito Extermination Society. Nov., 1904, 25 pp. and supplements.

Whitney, C. P.

Descriptions of Some New Species of Tabanidae. Canad. Ent., XXXVI, 205-207; July, 1904.

New: *Chrysops lupus* and *pikei*, *Tabanus benedictus* and *typhus*.

ADDITIONS AND CORRECTIONS.

The following papers are to be added to the bibliography:

Coquillett, D. W.

Papers from the Hopkins-Stanford Galapagos Expedition, 1898-1899.
Diptera. Wash. Acad. Sci., III, 371-379; Nov. 7, 1901.

Contains a small list of Diptera; one of the new species, *Canace snodgrassi*, was afterward reported from N. A., and will be found in the catalogue.

Marten, John.

New Tabanidae. Canadian Entomologist, XIV, 210-212; Nov., 1882.

Contains the following four species (synonymy by Hine): *Tabanus californicus* (syn. of *epistates*), *T. haemophorus* (syn. of *sotonensis*), *T. captonis* (of which *comastes* is a syn.), and *T. centron* (from Col.; the second form of *rhombicus*, in Osten Sacken's Western Diptera, 218).

Piper, C. V., and Doane, R. E.

Insects injurious to Currants and Gooseberries. Bull. 36, Wash. Ex. Sta.; May, 1898.

Biology of *Rhagoletis ribicola* and *Epochra canadensis*; the entries are included in the catalogue.

Ricardo, Miss.

Several articles on Bigot's and Walker's types of Tabanidae, in Annals and Mag. of Nat. History, ser. 7, VIII.

Not seen; no new species.

Corrections:

Page 6, omit Lonchaeidae from the list of families, as it was finally united with Sarcophagidae.

Page 8, third line from bottom, for *opposia* read *opposita*.

Page 115, third line from top, for *Chiconomus* read *Chironomus*.

Pages 134 and 136, for *Aedes* and *Aedomyia* read *Aëdes* and *Aëdomyia*.

Page 264, *Deromyia cuantlensis* should be *cuautlensis*, and the locality Cuantla, Mex., wherever occurring, should be changed to Cuautla; see Townsend, Annals and Mag. Nat. Hist., ser. 6, XX, 279.

Page 287, *Agonosoma tener* should be *tencrum*.

Page 319, add the following species under *Leptopeza*:

disparilis MELANDER, Monogr. Empid., 258, f. 69.—Cal., Ida.

Page 321, for *Empis aërobaticus* read *Empis aërobaeticus*.

Page 664, line 6, *Limnophora sacta* had already been reported by Van der Wulp under the genus *Leucomelina*.

PREFACE

Professor Leidy for some time previous to his death had in contemplation the publication of a work upon Helminthology and Parasitology. As is well known, for many years he was the only American naturalist who devoted any considerable time to the study of parasitology.

To students engaged in similar lines of investigation no apology is needed for the present volume. The subject-matter which forms the basis of the edition consists of verbal communications, short papers, and elaborate memoirs which have appeared from time to time (1845-1891) in the Proceedings and Journal of the Academy of Natural Sciences, Philadelphia ; the Transactions of the American Philosophical Society, the Smithsonian publications, and scientific journals.

The material has been arranged serially as it appears from the author's pen ; no attempt at classification could be made without destroying the character of the work. It was a long time before the editor could be induced to undertake the preparation of such a publication ; frequently he was tempted to place his pen aside, knowing full well that Professor Leidy had very little sympathy for compilations. The frequent and constant requests from investigators along similar lines of scientific research, however, for detailed information of the work under consideration has induced him to forego any personal feeling in the matter and allow the work to go forward.

For the use of students the editor has appended a working bibliography of Professor Leidy's contributions to science. Although care has been taken in its preparation, for any omission that may be found the editor asks the indulgence of the reader.

JOSEPH LEIDY, jun^r.

RESEARCHES IN HELMINTHOLOGY AND PARASITOLOGY

BY JOSEPH LEIDY, M. D., LL. D.

WITH

BIBLIOGRAPHY OF HIS CONTRIBUTIONS TO SCIENCE

ARRANGED AND EDITED BY JOSEPH LEIDY, JR., M. D.

[September, 1846. No. 9. See Bibliography.]

DESCRIPTION OF A NEW GENUS AND SPECIES OF ENTOZOA.*

In the course of an investigation of the anatomical structure of the terrestrial gasteropoda of the United States, I discovered a microscopic entozoon inhabiting the fluid contained in the vessie copulatrice or spermatheca of *Helix albolabris*, since which I have found it to exist in two other species, *Helix tridentata* and *Helix alternata*, and I have no doubt of its existence in others, not yet having had an opportunity of examining further. As there appears to be no known genus in which this animal can be placed, I have been necessitated to form the following :

Cryptobia.†—Animal minute ; form exceedingly proteoid ; internal organization cellular or granular.

C. helicis.—Colourless ; form ordinarily elongate, ellipsoid, fusiform, or ovate ; caudae opposite, one longer than the other. Internal granular structure consisting of two large cells and numerous minute granules. Total length from the 125th to the 100th of a line. Habitat, the vessie copulatrice or spermatheca of *Helix albolabris*, *Helix tridentata*, and *Helix alternata*.

The name of this genus is derived from *κρυπτός*, hidden, and *βίων*, to live. This singular entozoon in its general appearance and or-

* When not otherwise specified the extract is taken from the Proceedings of the Academy of Natural Sciences, Philadelphia.

† See Proc. Acad. Nat. Sci., Vol. III, August, 1847.

ganization appears to be intermediate between *Cercaria seminis* and *Filaria*. Its varied form and movements are curious to observe ; at one moment globular, then oval, ovate, fusiform, sigmoid, crescentic, &c., it appears as if it would outvie the kaleidoscope in its changes. The motions are vibratile, rotary, with a lateral progression, or whirling in circles like the insect *Cyrrinus*.

Cryptobia helcis might be confounded with the spermatozoa of the animal in which they are parasitic, on account of the organ in which they are found being connected with the generative apparatus, and its supposed use as a spermatheca, but they may be readily distinguished ; the spermatozoa of Helices generally having either a uniform sigmoid or a beaded body, with an enormous proportionate length of tail, and a slow, vibratile motion. It may be well to mention that *C. helcis* does not exist in the collapsed state of the generative organs.

[Some of the principal forms of the animal are represented in a sketch.]

[October. 1846. No. 11. See Bibliography.]

Dr. Leidy stated that he had lately detected the existence of an Entozoon in the superficial part of the extensor muscles of the thigh of a hog. The Entozoon is a minute, coiled worm, contained in a cyst. The cysts are numerous, white, oval in shape, of a gritty nature, and between the 30th and 40th of an inch in length.

The Entozoon he supposes to be the *Trichina spiralis*, heretofore considered as peculiar to the human species. He could perceive no distinction between it and the specimens of *T. spiralis* which he had met with in several human subjects in the dissecting-rooms, where it has also been observed by others, since the attention of the scientific public have been directed to it by Mr. Hilton and Professor Owen.

Dr. Leidy also exhibited a singular knotted mass of living Gordii or hair worms, with numerous long strings of ova attached, which had been taken a few days since from one of the hydrants of this city.

[June. 1847. No. 17. See Bibliography.]

Dr. Leidy exhibited a drawing of an Entozoon (a species of *Distoma*) found in the pericardium of *Helix alternata*. This Entozoon is half a line in length by a quarter of a line in breadth, a large comparative size, when its situation is considered, being equal to that

of the ventricle of the heart. The pericardium was perfectly transparent, and presented no appearance of cicatrix, or marks of external communication. Dr. Leidy then read the following description of

Distoma helicis.—Oval, flattened, white in colour; oral disk large, round, marked by radiating lines; posterior disk central, about the size of that of the mouth, radiate, with a dark spot in the center. Intestinal canal commencing by a fusiform œsophagus, the apex of which joins a round stomachal cavity, from which passes off on each side a convoluted intestinum, which proceeds to the posterior extremity of the body. About half way between the central disk and the posterior extremity of the animal, I indistinctly observed what I presumed to be the generative orifice.

[**August, 1847. No. 20. See Bibliography.**]

Dr. Leidy requested permission, which was given, to change the name of a new genus of Entozoa, described by him in Vol. 3, No. 5, of the Proceedings, from that of *Cryptobia* to *Crypticus*, the former name having been preoccupied.

DESCRIPTION AND ANATOMY OF A NEW AND CURIOUS SUBGENUS OF PLANARIA.

In October, 1840, Prof. S. S. Haldeman published a description of an animal under the name of *Planaria gracilis*.* Upon examination I detected such a remarkable peculiarity in the digestive apparatus as led me to investigate its anatomy in detail, and to form for it a separate subgenus, characterized as follows:

Phagocata, oblonga, plano-convexa, nuda, contractilis, muscosa, antica auricularia. Aperturæ duæ, ventrales, ad os et generationem pertinens. Proboscides multæ.

P. gracilis, nigricans, lateribus parallelis, postero acuto abrupte, plerumque antico recto; oculis duobus. Long., 9 lin.; lat., 1 lin. Habitat in fontis Pennsylvaniæ.

Description.—Oblong, limaceform, naked, convex superiorly, flat inferiorly very contractile; sides ordinarily parallel, convex when the animal is in a contracted state, convergent anteriorly when elongated; anterior extremity with a lateral triangular auricular appendage,

* Supplement to number one of "A Monograph of the Limniades, or Fresh-water Univalve Shells of North America," containing descriptions of apparently new animals in different classes, &c. By S. S. Haldeman. Philadelphia, 1840.

straight in front, by contraction becoming convex or concave; posterior extremity abruptly pointed; ocelli two, anterior, composed of an oblong, semi-transparent (nervous?) mass with an intensely black dot of pigmentum at the internal posterior part; ventral apertures two; oral aperture a little less than one-third the length of the body from the posterior extremity, and very dilatable; generative aperture half-way between the oral aperture and posterior extremity. Colour black or iron gray, and in some younger specimens latericeous. This animal I have only found in abundance in the neighborhood of Professor Haldeman's residence, near Columbia, Pa. In a spring in front of his house, thousands of them may be seen gliding along the bottom; some of them occasionally creep up the sides to the surface of the water, turn upon their back, and by making the ventral surface concave, float about in the manner of the Limniadæ. It appears to be carnivorous in habit, or at least it attaches itself to animal matter, dead or living, in preference to vegetable matter. When irritated it throws out a considerable quantity of very tenacious mucus.

In structure it appears to be intermediate between the entozoic Distomata and the annulose Hirudinæ. I could not detect any trace of annulation, but I think that this alone would hardly be sufficient to place it lower than the latter animals, because, in a closely allied animal, the *Gordius aquaticus*, although there is no annulation in the perfect animal, yet in the embryo state I find it to exist.

The whole animal is composed of a delicate granular structure; the only approach to muscular fibre is in the longitudinal striation of the integument rendered more distinct by the pigmentum nigrum, a radiated appearance around the oral orifice, and a faint transverse and longitudinal arrangement of the granules entering the composition of the proboscides, seen more or less distinctly in the continued movement of these organs when slightly compressed beneath the microscope.

The digestive cavity presents the same dendritic arrangement as in Planariae generally,* but instead of possessing a single sucker or proboscis, the full-grown animal has not less than twenty-three; varying, however, in this respect from three upwards, according to the age of the animal. One of these proboscides joins the digestive cavity at the posterior part of the anterior division, as usual; the others join the remaining two divisions at their internal side in their course backward. They are considerably longer but narrower than

* Dugès An. Sc. Nat.

in *P. lactea*,* and when not in use are closely packed together within the animal, so that when the latter is placed beneath the microscope and slightly compressed, they will be seen pressing upon one another in such a manner that if one changes its position it will be instantly occupied by another. Those which are formed last are smallest, but they soon gain their full size.

When the animal feeds, the whole of them are protruded from the oral orifice, the longest extending out full one-third the length of the body. As they are all convergent to the same orifice, when fully protruded the animal becomes puckered up and increased in breadth at the expense of the length. In this state the anterior extremity is erected and the posterior brought nearly to a right angle with it, so that it looks as if sitting upon its prey apparently unconcerned, with its proboscides, which writhe and twist about as if they were totally distinct organisms.

If one of these animals be punctured or cut, one or more of the proboscides will be immediately protruded as if they existed under pressure, and will move about in all directions, appearing as if entirely without the control of the animal ; or if one of the animals be crushed between two slips of glass, so that the proboscides will be torn from their attachment, they move about involuntarily, always in a line forwards or towards the mouth, which they do by contracting the stomachal extremity towards the oral, the latter remaining fixed. In this progressive course they constantly contract and dilate ; the mouth opens and any matter in its vicinity rushes in, when it is closed and the matter passes onwards, and by the alternate contraction and dilation of different parts of the same tube, it is thrown backwards and forwards several times and finally violently expelled at the torn extremity. When they have escaped from the ruptures of the tegument produced by crushing, or when snipped off with a pair of scissors whilst an animal is feeding, they will present the same curious phenomena. In fact these curious independent movements caused me at first to mistake the organ for viviparous young, and it was not until I had frequently observed the animal feeding, and examined its structure beneath the microscope, after having fed them upon coloured food, that I was convinced of their true nature.

Excrementitious matter is expelled from the digestive cavity through the same course by which the food enters.

Circulation.—There appears to be nothing peculiar about the arrangement of the blood vessels, if such they be : the term being

* Ibid.

applied to two semi-transparent lines passing along each side of the ventral surface, and a third along the middle of the dorsal surface, the three freely communicating with each other by transverse lines and numerous smaller branches, the whole forming an extensive reticulation upon the surface of the body. At the anterior part of each ventral line I distinctly observed a dilatation to exist.

Generative apparatus.—As in all Planariae, the animal is androgynous. The penis is a bulbiform organ placed between the oral and generative orifice, with its point directed toward the latter. The point is straight, or contorted; the bulbous portion is also changeable, sometimes elongated, at others flattened or increased in breadth at the expense of the length. The bulb shows through the thin integument, and without close examination may be taken for a third orifice. The penis is perforate, and has a dilated cavity within the bulb. Immediately above the penis I indistinctly observed a somewhat lobated organ, which appeared to join the penis at its base by a narrow portion. This is probably the testicle, for it was the only thing I could discover in connection with the genitalia to correspond to it.

In two individuals only could I see part of the female organs. This consisted in two sigmoid tubes or oviducts, which could be traced from the generative orifice a short distance forward, one on each side of the penis.

I could detect no traces of a nervous system.

The eyes, so called, have been previously described. It is still a question with many, whether these, as well as the corresponding deep black points existing in very many of the lower animals of the invertebrate series, subserve the purpose of eyes; and some anatomists have even gone so far as to deny the sense of sight to the comparatively perfect eye of many gasteropodous mollusca. The experiments which are made to test the existence of this sense in these organs for the most part are exceedingly fallacious, generally being performed by concentrating the light upon them through a lens. Insects, and even serpents and frogs, I find will frequently bear the impression of a sudden glare of light produced in this way without any inconvenience, at other times they will seek to avoid it, but *Helix albolabris* will occasionally retract its tentacle when so disturbed, and *Phagocata* will frequently raise its interior extremity and move from the too great light. From their position, which is always such as to be well exposed to the influence of the light, from their structure, imperfect as it is in many cases, and their connection with the nervous system when this exists, I am led to conclude that in all cases they are organs of vision.

The general sensibility of *Phagocata* is very considerable, that is, it contracts with great readiness from the slightest disturbance. The contraction has much the appearance of being involuntary and is very like that of the medusæ. When an individual is irritated at any point, contraction commences there, and thence rapidly extends throughout the animal, and the only appearance of volition is in the effort to escape, but if the touch be too rude, apparently involuntary contraction takes place suddenly and appears to destroy all power of volition for the moment; the animal, however, soon revives from this state and glides off with its accustomed speed.

Some experiments which I performed upon *Phagocata* confirm the statement that the Planariae are capable of repairing injuries. When an individual is cut into two, both parts after a time become distinct and perfect animals. Division carried to a greater extent in some instances results in as many perfect animals as there are parts, but generally I have found that when cut into more than three or four pieces, the intermediate pieces are apt to die, and sometimes the extremities do not survive.

I exhibit a drawing of *Phagocata gracilis*, from Prof. S. S. Haldeman.

A drawing of two individuals feeding upon a piece of *Lumbricus*.

Do., representing the ventral surface with the proboscides protruded.

Do., representing the digestive and generative apparatus.

Do., representing five of the proboscides highly magnified.

[**August. 1847. No. 21. See Bibliography.]**

DESCRIPTIONS OF TWO NEW SPECIES OF PLANARIA.

Planaria maculata.—Superiorly convex, faintly blackish or brownish with irregular colourless maculae; inferiorly flat, colourless; anteriorly trapezoidal; posteriorly spatulate or oval; eyes two, anterior, proximate, composed of a large semi-transparent mass with a reniform mass of pigmentum nigrum at the postero-internal part; oral aperture ventral, one-third the length of the body from the posterior extremity; proboscis large and cylindrical. Length $2\frac{1}{4}$ lines; breadth $\frac{1}{2}$ line. Found in moderate abundance, in the ditches below the city, creeping upon the submerged stems of aquatic plants.

Subgenus. *Prostoma*, Dugès. Mouth anterior and terminal.

Prostoma marginatum.—Blackish, narrow lanceolate, anteriorly truncate; marginate, margin delicately striate; mouth large; pro-

boscis large and oblong : eyes two, anterior, distant, each consisting of two round masses of pigmentum nigrum in contact with each other, and of which one is longer than the other ; generative orifice one-fourth the length of the body from the posterior extremity. Length 1 line. A single specimen found with the preceding ; but probably not rare, for, from its small size, it escaped my notice while collecting some of the former, and it was not until I got home that I detected its existence in the vessel of water containing the others.

The anatomy of *P. maculata* does not differ from that of *Planaria lactea* as given by Dugès in the Annales des Sciences Naturelles. In *Prostoma marginatum* the digestive cavity has not the dendritic arrangement of Planaria, but merely consists of a large capacious sac extending as far back as the posterior third of the body, and having a cæcum upon each side of the proboscis. The penis has a yellow colour and consists of a round granular mass, with a moderately long and bent spiculum projecting from its posterior part. The arrangement of the female apparatus I failed to trace.

[October, 1849. No. 40-44. See Bibliography.]

From the opinion so frequently expressed that contagious diseases and some others might have their origin and reproductive character through the agency of cryptogamic spores, which, from their minuteness and lightness, are so easily conveyed from place to place through the atmosphere, by means of the gentlest zephyr, or even the evaporation continually taking place from the earth's surface ; and from the numerous facts already presented of the presence of cryptogamic vegetation in many cutaneous diseases and upon other diseased surfaces, I was led to reflect upon the possibility of plants of this description existing in healthy animals, as a natural condition ; or at least apparently so, as in the case of entozoa. Upon considering that the conditions essential to vegetable growth were the same as those indispensable to animal life, I felt convinced that entophyta would be found in healthy living animals, as well, and probably as frequently, as entozoa. The constant presence of myco-dermatoid filaments growing upon the human teeth, the teeth of the ox, sheep, pig, etc., favored this idea, and accordingly I instituted a course of investigation, which led to the discovery of several well characterized forms of vegetable growth, of which, at present, I will give but a short description, for the purpose of establishing priority, and propose giving a more detailed account of them, with figures, in the second volume of the Journal.

*Enterobrus,** a new genus of Confervaceæ.—Simple, attached, isolated filaments consisting of a large cylindrical cell, (containing protoplasma, granules, and large translucent globules enveloped in a primordial utricle,) with a distinct coriaceous peduncle or stipe of attachment, and at length producing at the free extremity one or two, rarely three, shorter cylindrical cells, (filled with the same matter as the parent cell.)

Enterobrus elegans.—Filaments, olive brown, brownish, yellowish, or colorless, at first forming a single spiral turn, and then passing in a straight or gently curved line to the free extremity. Peduncle, or stipe of attachment, adhering very firmly, coriaceous, uniformly, brownish, narrower than the frond cell, papillary, columnar, elongated conical or pyramidal, expanded at base and at point of attachment to frond cell, marked with longitudinal lines, and frequently with transverse annular constrictions, with no definite interior structure. Length from 1-3750th to 1-400th of an inch; breadth 1-3200th to 1-1666th. Frond cell inch elongated, frequently reaching the length of 2 or 3 lines, uniformly cylindrical, excepting at free extremity, where it is usually clavate; breadth in full grown individuals pretty uniformly 1-935th of an inch. Contents consisting of a colorless protoplasma, with more or less numerous fine, translucent, yellowish or colorless granules, measuring about 1-15,000th of an inch, and numerous large, colorless, transparent globules or vesicles filled with fluid, averaging the 1-2870th of an inch in diameter. End cells only existing in full grown individuals, one, usually two, rarely three in number; the first one cylindrical, 1-86th of an inch in length by 1-1000th in breadth, filled with more granules and less globules than the parent cell; end cell clavate, 1-135th of an inch long by 1-750th broad, at the clavate end 1-638, filled with granular matter and a few globules.

Length of full grown individual 2 to 3, sometimes 4, lines.

Habitat.—Grows from the basement membrane of the mucous membrane of the small intestine of *Julus marginatus*, Say, occasionally from the same membrane at the commencement of the large intestine and also from any part of the exterior surface of *Ascaris infecta* and *Aorurus*: entozoa infesting these portions of the intestinal canal of this animal.

The youngest individuals of *Enterobrus* which I ever detected measured 1-380th of an inch in length by 1-1060th in breadth, but the most usual sizes vary from the 1-150th of an inch to the full

* *Enterobrus* :—Ἐντερός et βρῶς.

grown individual. At all ages they contain the same character of contents, but in the younger ones the large globules are usually predominant, sometimes to such an extent as to exclude the other matters. When quite young they are usually more or less clavate and straight, a little more advanced they form a gentle curve, about one-eighth of a circle. A little older, the distal half or third becomes uniformly dilated, and forms an obtuse angle with the other portion; after this as it continues growing, it usually forms a single spiral turn, becomes uniformly dilated, and thus advances to the full-grown individual. The cell contents consist principally of large transparent globules with granules and protoplasma in the interstices. Frequently the cells are found distended with the globules to such an extent that the other matters almost, and occasionally even entirely, disappear. Iodine turns the protoplasma and granules deep yellow or very deep brown, and causes the rupture of the granules, when a clear fluid is observed to exude, very slightly colored purplish, or undergoing no change of color from the iodine. Solution of iodine, acetic acid, salt water, or the prolonged action of water alone, causes a contraction of the cell contents from the sides of the permanent cell wall, but they are still held together by an apparent delicate membrane of the character of a primordial utricle. Frequently in dead individuals the interior contents shrink to two-thirds, occasionally to one-third the diameter of the cell calibre, and almost 8 to 20 times the diameter of the cell from each extremity, when they have the appearance of a shriveled granular membrane. In these latter cases the characteristic globules and granules have disappeared, and their place is more or less occupied with water, and yellowish globular, highly refractive bodies, which resemble oil. These latter globules vary in size from a mere point to one-fourth the diameter of the cell. The smaller ones are contained within the shriveled primordial utricle with a few of the larger ones, and a number of the latter occupy a position between the primordial utricle and the cell wall apparently formed by a conjunction of the smaller globules and an exudation through the primordial utricle during the act of contraction consequent upon decomposition. They are insoluble in alcohol, but are soluble in ether or a solution of potassa; in fact in all their properties they resemble oil. Can these be oil globules the result of decomposition?

The protoplasma or fluid of the cells is colorless or faintly yellowish, contracts or coagulates upon the application of alcohol, and is colored brown by iodine, having all the characters usually possessed

by that albuminoid fluid found in all young vegetable cells and denominated protoplasma by H. von Mohl.

The clear granules are minute, yellowish and resemble fine oil globules. They are turned deep brown by the action of iodine.

The clear globules appear to consist of a delicate vesicular membrane probably derived from the primordial utricle, filled with colorless fluid.

No circulatory or other movement as in *Achyta prolifera*, exists in the cell contents. The end cells of the full-grown individuals are usually two in number, and much shorter than the parent cell. Occasionally I have found three end cells, more frequently but one. These cells are formed by the parent cells, by a contraction first taking place in the contents with the primordial utricle, a partition from the permanent cell wall forming afterwards.

The end cells are probably spore cases; their contents are usually a dense mass of fine granules, similar to those of the parent cell, with a few intermingled globules. I never saw any movement, either molecular or other, in the contained matter, except during decomposition.

A question may arise as to the true situation of this plant among the cryptogamia. I have placed it in the order Confervaceæ, from the diagnosis given by Endlicher, in his *Genera Plantarum*: "Fila capillaria, membranacea v. filamentosa, intus v. extus articulata, simplicia v. ramosa, libera (*i. e.* haud in frondem coalita), interdum tamen reticulatim contexta, viridia v. rarius fusca aut purpurea, in formis infinitis hyalina, etc."

Cladophytum,* a new genus of entophyta allied to the Mycodermata. Filaments minute, attached by means of a roundish nucleous, simple, or compound near the base of attachment, with minute lateral ramuli, inarticulate, and with no evidence of interior structure.

Cladophytum comatum.—Filaments delicate, regular, colorless, simple, more frequently branched near the base at very acute angles, growing in more or less dense bunches from a yellowish rounded or oval, attached, nuclear body varying in size from 1·7500th to 1·600th of an inch. Lateral ramuli very minute, measuring in length from 1·1500th to 1·3000th of an inch, and passing off at acute angles. No indication of articulation or interior structure.

Length from 1·666th to 1·120th of an inch.

Habitat.—growing more or less profusely from the mucous membrane of the small intestine of *Julus marginatus*, occasionally from

* *Cladophytum* :—*κλαδός* et *φύτος*.

the same surface at the commencement of the large intestine, from any part of the exterior surface of entozoa infesting those cavities, and also from any part of the surface of *Enterobrûs elegans*.

Arthromitus,* a second new genus of entophyta, allied to the Mycodermata.—Filaments always simple, cylindric, articulated, without ramuli, attached by means of a nuclear body, and with no evidence of interior structure.

Arthromitus cristatus.—Filaments delicate, straight or inflected, growing in tufts usually of moderate density, from minute, attached, yellowish rounded or oval nuclear bodies. Articuli short, cylindric, uniform, measuring 1-9090th inch in length by 1-15,000th in breadth, with no traces of interior structure.

Length 1-375th to 1-46th of an inch, breadth 1-15,000th inch.

Habitat.—Same as *Cladophytum comatum*, but rarely growing in such dense tufts.

The three genera of entophyta of which I have now spoken are all so constantly found in *Julus marginatus* that I look upon it as a natural condition, and should I hereafter meet with an individual without them, I will consider it a rare exception, because in one hundred and sixteen individuals which I have examined during the past thirteen months, in all seasons, and at all ages and sizes of from one up to three inches of the animal, I have invariably found them. It cannot be supposed that these are developed and grow after death, because I found them always immediately upon killing the animal. Whilst the legs of fragments of the animals were yet moving upon my table, or one-half of the body even walking, I have frequently been examining the plants growing upon part of the intestinal canal of the same individual. And upon the entozoa these entophyta will be frequently found growing, whilst the former are actively moving about. I found among others an ascaris three lines long, which had no less than twenty-three individuals of *Enterobrûs*, averaging a line in length, besides a quantity of the other two genera, growing upon it, and yet it moved about in so lively a manner that it did not appear the least incommoded by its load of vegetation. This specimen I have preserved in a glass cell in Goadby's solution, and exhibit it to the Academy.

The animals were uniformly enjoying good health, *i. e.*, all the organic and animal functions were natural; they ate, grew, reached their definite size, reproduced, and in fact presented all those actions characteristic of the normal state of existence of the animal.

The genus *Julus* is an extensive one, and its species are found in all the great parts of the globe, and as their habits are the same, the conditions for the production of the entophyta will be the same, and I think I do not go too far when I say they will be constantly found throughout the genus in any part of the world, so that naturalists and others may, upon examination, readily verify or contradict the statements which I have this evening presented.

From these facts we may perceive that we may have entophyta in luxuriant growth within living animals without affecting their health, which is further supported by my having detected mycodermatoid filaments in the cæcum of six young and healthy rats, examined immediately after death, although they existed in no other part of the body. These filaments were minute, simple and inarticulate, measuring from 1-5000th to 1-1428th inch in length by 1-16000th of an inch in breadth. With them were also found two species of *Vibrio*.

Even those moving filamentary bodies belonging to the genus *Vibrio*, I am inclined to think, are of the character of algous vegetation. Their movement is no objection to this opinion, for much higher conservæ, as the Oscillatoriæ, are endowed with inherent power of movement, not very unlike that of the *Vibrio*, and indeed the movement of the latter appears to belong only to one stage of its existence. Thus, in the toad, (*Bufo americanus*.) in the stomach and small intestine, there exist simple, delicate, filamentary bodies, which are of three different kinds. One is exceedingly minute, forms a single spiral, is endowed with a power of rapid movement, and appears to be the *Spirillum undula* of Ehrenberg : the second is an exceedingly minute, straight, and short filament, with a movement actively molecular in character, and is probably the *Vibrio lincola* of the same author ; the third consists of straight, motionless filaments, measuring 1-1125th inch long by 1-15000th broad : some were, however, twice or even thrice this length ; but then I could always detect one or two articulations, and these, in all their characters, excepting want of movement, resemble the *Vibrio*. In the rectum of the same animal, the same filamentary bodies are found, with myriads of *Bodo intestinalis* : but the third species, or longest of the filamentary bodies, have increased immensely in numbers, and now possess the movement peculiar to the *Vibrio lincola*, which, however, does not appear to be voluntary, but reactionary ; they bend and pursue a straight course, until they meet with some obstacle, when they instantly move in the opposite direction, either extremity forward.

But it must not be understood that these facts militate against the hypothesis of the production of contagious diseases through the agency of cryptogamia. It is well established that there are microscopic cryptogamia capable of producing and transmitting disease, as in the case of the Muscardine, &c., as that there are innocuous and poisonous fungi. But to suppose that they are the sole cause of contagious disease is to doubt the possibility of other causes, such as change in the chemical constitution of the atmosphere, the elements of our food, &c., and is as ridiculous as the psoric origin of most diseases of that miserable charlatanry denominated homœopathy. In many instances it is difficult to distinguish their character whether as cause or effect, as upon diseased surfaces, in *Tinea capititis*, aphous ulcers, &c. In a post-mortem examination, in which I assisted Dr. Horner, a few weeks since, 28 hours after death, in moderately cool weather, we found the stomach in a much softened condition. In the mucus of the stomach, I detected myriads of mycodermatoid filaments, resembling those growing upon the teeth; simple, floating, inarticulate, and measuring from 1-7000th to 1-520th of an inch in length by 1-25,000th of an inch in breadth. It is possible that they may have been the cause of the softened condition; but I would prefer thinking that swallowed mycodermatoid filaments from the teeth, finding an excellent nidus in the softening stomach, rapidly grew and reproduced themselves. In the healthy human stomach these do not exist.

In the stomach of a diabetic patient, I found so very few that they probably did not grow there, but were swallowed in the saliva.

Dr. Leidy, after exhibiting numerous drawings of the entophyta described by him, and also specimens, beneath the microscope, growing from the mucous membrane of the small intestine *Julus*, and from the exterior surface of entozoa infesting that cavity, proceeded to exhibit and describe some new genera and species of entozoa, as follows:

1. *Iscaris cylindrica*.—Body nearly cylindrical throughout, anteriorly moderately attenuated; tail curved, 1.214 of an inch in length from the anus, œsophagus elongated, gibbous in the middle, with the œophageal bulb and pharynx 1-100th of an inch in length; œophageal bulb pyriform, 1-75th of an inch in diameter; ventricle or intestine somewhat tortuous, cylindrical, dilated at both extremities; rectum pyriform; female generative aperture about half way between the mouth and tail. Whole length 4-5th of a line, breadth 1-12th of a line.

Habitat.—Small intestine of *Helix alternata*.

Remarks.—I found the female only of this species in fifteen out of forty specimens of *Helix alternata*, in numbers of from one to three. The ovaries in all were distended with ova, the latter measuring 1-430th of an inch in length by 1-576 in breadth.

a. *Ascaris infecta*.—Female, subcylindrical gradually diminishing toward the extremities, white, with brown streak down the lower two-thirds of the middle line; anteriorly obtusely rounded; tail slightly curved, 1-80th of an inch long from the anus. The three papillæ of the mouth projecting; œsophagus strongly muscular, thick, oblong, pyriform, 1-80th of an inch long, greatest breadth 1-175th of an inch; œsophageal bulb, cordiform, 1-166th of an inch long, by 1-166th of an inch broad, ventricle slightly dilated at commencement, contracted posteriorly; generative orifice projecting just below the middle of the body. Vagina furnished with a large ovate seminal receptacle.

Male, dilated at both extremities; tail thick, 1-174th of an inch long, furnished upon its inner aspect with two minute tubercles. Above the anus are two rows, each of four tubercles, connected by delicate folds of integument. œsophagus 1-111th of an inch long, 1-260th of an inch broad; œsophageal bulb depressed cordiform 1-214th of an inch long, by 1-250th of an inch broad. Penis formed of two curved spiculæ, measuring in length in a straight line 1-78th of an inch.

Length of adult female 3 to $4\frac{1}{2}$ lines; breadth at origin of ventriculus 1-123d of an inch; middle of body 1-83d to 1-60th of an inch; just above anus 1-144th of an inch. Ova 1-319th of an inch long by 1-428th inch broad.

Length of male 2 lines; breadth at origin of ventriculus 1-176th of an inch; middle of body 1-211th of an inch; just above anus 1-202d of an inch. Spermatophori oval, 1-1391st inch long, by 1-1666th inch broad, with spermatozoa 1-3750th inch long, by 1-10000th inch broad.

Habitat.—This species is found in numbers from three to fifty or more, of various ages and sizes, pretty constantly in the small intestine of *Julus marginatus* Say. The males are found in the proportion of about one in eight.

Aorurus,* a new genus of *Nematoideæ*. Body cylindrical, strongly annulated, with a tail nearly as long as the body, straight or nearly so, inflexible, spiculate, ensiform, shining, and pointed. Mouth unarmed. Female generative aperture near the middle of the body.

* Aorurus:—*Anus et oöpæ.*

Remarks.—This genus is divisible, by several well-marked characters, into two distinct sub-genera.

1st sub-genus. *Streptostoma*.^{*}—Body cylindrical, very strongly marked with broad annuli. Mouth moderately large, round, bordered by a collar (formed by the second annulus projecting beyond the general outline of the body). Oesophagus divided into two distinct pyriform muscular bulbs, with a small intermediate rounded bulb. Tail four-fifths the length of the body.

Streptostoma agile.—Female. Body larvaform, cylindrical, narrowed anteriorly and posteriorly, opalescent white, divided into from sixty-one to eighty-eight broad annulations, of which there are twenty-one from the mouth to the commencement of the ventriculus. Tail very straight, occasionally slightly sigmoid, or bent at the point, narrow and sharply pointed, inflexible and brittle. Mouth moderately large, round, projecting; pharynx almost null; oesophagus consisting of three bulbs: the first elongated pyriform, strongly muscular, measuring 1-197th inch long by 1-319th inch broad; second bulb small, rounded, muscular, 1-882d inch long by 1-882d inch broad; third or true oesophageal bulb, pyriform 1-294th inch long by 1-312th inch broad. Ventriculus dilated at commencement to nearly the diameter of the body, afterwards straight and cylindrical to near its termination, where it is slightly dilated. Rectum elongated, pyriform. Generative aperture situated about twenty-four rings above the anal aperture, which latter is placed between the last two annuli of the body. Ovary double; ova 1-333d inch long by 1-400th inch broad.

Length of body from 1-13 to 1-11th inch; breadth at commencement of ventriculus 1-118th inch; at middle of body 1-97 inch. Tail from 1-16 to 1-15th inch long by 1-888th inch broad at its middle.

2d sub-genus.—*Thelastoma*.[†]

Body cylindrical, attenuated anteriorly, strongly marked with moderately broad annuli. Mouth small, opening at the extremity of a small papilla. Oesophagus divided into two distinct portions, the first long and cylindrical, the second constituting the true oesophageal bulb. Tail more than half the length of the body.

Thelastoma attenuatum.—Female. Body attenuated anteriorly to commencement of the ventriculus, opalescent white, divided into from 140 to 160 annulations, of which there are from fifty-two to fifty-seven from the mouth to the commencement of the ventriculus.

* *Streptostoma* :—Στρεπτόστομος et στομα.

† *Thelastoma* :—Θελάστημα et στομα.

Tail very straight or very slightly curved or bent, slender, inflexible and brittle, and sharply pointed. Mouth always projected, small, surmounting a small papillary elevation formed by the first annulus of the body. Pharynx very short and narrow; oesophagus strongly muscular, cylindrical, 1-47th inch long, by 1-533d inch broad; oesophageal bulb pyriform, 1-178th inch long, 1-222d inch broad. Ventriculus dilated alæform, at commencement cylindrical throughout. Rectum short, pyriform. Generative aperture 42 annulations above the anal. Ovary double, ova 1-333d inch long by 1-400th inch broad.

Length of body from 1-10th to 1-8th inch; breadth at middle 1-95th inch. Tail 1-14th inch long by 1-111th inch broad at middle.

Habitat and Remarks.—*Streptostoma agile* and *Thelastoma attenuatum* are found together principally in the commencement of the large intestine of *Julus marginatus*, in numbers of from one to fifteen, and less frequently in the small intestine with *Ascaris infecta*, in numbers of from one to six. It is remarkable, that although I have found from one to fifteen of these two genera, in nine-tenths of the animals examined, I have never yet been able to detect a single male.

Thelastoma always has the mouth projected, whilst *Streptostoma* has it retracted, producing, in some measure, but by no means wholly, the difference in size of the oral aperture.

At first I was inclined to think that these two animals were different stages of the same species, but the adults uniformly correspond to the descriptions given, and in all cases contained more or less perfected ova.

Their movements are active, wriggling the body in a sigmoid manner and vibrating the delicate spiculated tail, which in sunlight resembles a shining acicular crystal.

Thelastoma, from its form of oesophagus and narrower annulations and shorter tail than *Streptostoma*, occupies a position between the latter and *Oxyuris*.

Gregarina, Dufour.

Body consisting of two distinct cells. Inferior cell the larger, marked with delicate parallel, longitudinal lines, (muscular?) and filled with a fine granular matter, obscuring one or two nucleo-nucleated organic cells. Superior cell placed in a depression of the inferior, surmounted by a slight papilla in which may be detected two lines, apparently outlines, of an oral canal to the interior of the cell which is filled with granular matter; cell wall amorphous and transparent.

Gregarina larvata.—Body opaque white, cylindrical or fusiform, frequently considerably dilated at the middle of the upper third. Superior cell a flattened or depressed sphere, received about one-half into a depression of the inferior cell, surmounted by a papillary elevation with traces of a communication with the exterior; interior filled with a finely granular mass resembling oil globules, and measuring from 1-1500th to 1-7500th inch. Length of cell, in smallest individuals 1-123d inch; in largest 1-80th to 1-61st inch broad. Inferior cell elongated, cylindrical or fusiform, not communicating with the exterior nor with the interior of the superior cell; filled with a mass of granules resembling that of the superior cell, rendering the larger individuals opaque, but translucent in the smaller ones, and usually obscuring one or two comparatively large nucleolo-nucleated organic cells, measuring from 1-888th to 1-308th inch in diameter. Cell-wall marked with exceedingly regular, delicate, longitudinal, parallel lines about 1-9375th inch apart, apparently muscular in character.

Length from 1-160th to 1-30th inch by 1-830th to 1-111th inch in breadth.

Habitat.—Found in numbers from half a dozen to over a hundred, in the ventriculus of *Julus marginatus*.

Gregarina is probably the larva condition of some more perfect animal, but in the 116 individuals of *Julus* which I have examined, I have not been able to detect any form which could be derivable from it. Creplin doubts its *animality*.* When I first discovered this body, thinking it to be a larva, I did not examine it carefully, and it was not until sometime afterwards when, being desirous of ascertaining its true nature, upon examining some fresh specimens beneath the microscope, I detected movements of an animal character, and this led me to seek for muscular structure, which resulted in the discovery of the longitudinal lines of the inferior† cell. These escaped the observation of Siebold, for he says, "Nach meine Beobachtungen bestehen die Gregarinien aus einer harten glatten den Eihüllen der Insekten-Eier ähnlichen Haut."‡ The movements of the animal are exceedingly sluggish, and consist of a very slow bending in any direction of any part of the inferior cell, most usually above the middle, rarely at the inferior extremity, but most frequently near

* Nachträge zu Gurlt's Verzeichniss der Thiere bei welchen Entozoen gefunden worden sind. Wiegmann's Archiv, 1846, 1 Band, S 157.

† Wiegmann's Archiv, 1838, 2 Band, S 308.

‡ See May, 1851. Dr. Leidy observed similar muscular structure (Proc. Acad. Nat. Sci., No. 76, in Bibliography) in the superior division.

the superior cell, which is entirely passive. The superior cell is also frequently drawn or contracted within the inferior, and again protruded by the contraction of the latter, and the propulsion of the granular contents against it. The inferior cell is also frequently, more especially in younger individuals, intussuscepted within itself through a partial contraction; and again relieved by a general contraction of the cell-wall.

In the state in which *Gregarina* is found, it would probably hold a rank between the *Trematoda* and *Trichina*, the lowest of the Nematoida.

Nyctotherus,* a new genus of Polygastrica, allied to *Plesconia*.—Body ovate, dilated posteriorly, compressed anteriorly, granulated, longitudinally lined, with an apparent operculum covering its anterior half, and having a semicircle of cilia just within its margin inferiorly and posteriorly. Center of the operculated portion furnished with a large trapezoidal finely granular areola. Posterior part of the body with a short fissure passing inwards and downwards.

Nyctotherus velox.—Body white, ovate, conoidal, anterior margin rounded, obtuse; posteriorly acute. Posterior margin of the apparent operculum passing in a curved line upwards upon the middle of the body to within a short distance of the back, and furnished inferiorly with a point projecting backwards, with a line passing down from the back about the middle of the operculum to the trapezoidal areola, giving the part of the body anterior to this the appearance of a head. Trapezoidal areola, with curved sides, finely granular. Posterior fissure communicating with the exterior, just above the acute termination of the body, and passing inwards and downwards, resembling an anal aperture. Areolæ of the interior sarcous mass generally minute, one large and round pretty constantly to be observed at the inner termination of the posterior fissure.

Length from 1-254th to 1-180th inch; breadth from 1-320th to 1-254th inch.

Habitat.—Commencement of the large intestine of *Julus marginatus*, often found in considerable numbers.

Remarks.—This genus is closely allied to *Plesconia*, but possesses no appendages excepting the semicircle of cilia, just within the edge of the apparent operculum.

The animal swims in water with great ease and grace. After being in this fluid some time, the external investment bursts, and

* *Nyctotherus* :—Νυκτοθερός.

allows the protrusion of globular masses of sarcous matter, as in *Leucophrys*, but not to such a great extent.

NOTE:—Since the above went to press, Dr. Leidy announced to the Academy that he had discovered two new species of the entophyte *Enterobrus*: one of them, *E. spiralis*, 1-69th inch long, growing in the small intestine *Julus pusillus*; the other *E. attenuatus*, 1-24th inch long, growing more or less profusely with a second species of *Cladophytum*, *C. clavatum*, in the ventriculus of the coleopterous insect, *Passalus cornutus*. Thus has been established the law "that plants may grow in the interior of the healthy animal as a normal condition," and a new field has been presented for the investigation of the Cryptogamo-naturalist. [See forthcoming number of the Proceedings.]

[December, 1849. No. 45. See Bibliography.]

DESCRIPTIONS (ACCOMPANIED BY DRAWINGS) OF A NEW GENERA AND SPECIES OF ENTOPHYTA.

Enterobrus spiralis.—Yellowish, brownish, brown or hyaline, forming a single, double or triple spiral. Peduncle brownish or yellowish, columnar, 1-250th inch long by 1-600th inch thick: First or principal cell uniformly cylindrical, filled with granules and globules, 1-4285th inch in diameter. Penultimate cell cylindrical, filled with granules and a few globules, 1-428th inch long. End cell clavate, filled with granules, 1-535th inch long by 1-3333d inch at broadest part.

Length from 1-70th to 1-50th inch by 1-4200th inch broad.

Habitat.—Grows from mucous membrane of the small intestine of *Julus pusillus*.

Remarks.—This species is found in varying quantity from a half dozen individuals up to fifty or more of various ages. The specimens of *Julus pusillus* from which the plant was obtained measured half an inch in length.

Enterobrus attenuatus.—Faintly brownish, yellowish or hyaline, forming a double flexure or sigmoid curve, and then growing in a very straight course to its termination. Peduncle yellowish, columnar, sometimes double, 1-666th inch long by 1-2300th inch broad. Principal cell attenuated at both extremities, rounded or truncated at the distal end, and filled with varying quantity of globules and granules. End cells?

Length 1-24th inch; diameter at middle 1-1500th inch; at sigmoid curve 1-2300th inch; at distal extremity 1-2500th inch.

Habitat.—Grows in profusion from mucous membrane of the ventriculus of *Passalus cornutus*.

Remarks.—This is a very graceful form, and is more disposed to grow in bunches or close together than the other species. I have not met with it with the terminal two cells in twelve specimens of *Passalus*, which contained over a hundred of the plants, although from some of the individuals appearing truncated at the distal extremity, I think it probable that they may occur; otherwise it would form a distinct genus.

Cladophytum ramosissimum.—Filaments very long, very delicate and very much branched, growing in fasciculi of moderate density from granular masses.

Length 1-75th inch; thickness of principal filaments or trunks 1-15000th inch.

Habitat.—Growing in moderate profuseness from the mucous membrane of *Passalus cornutus*.

NEW GENUS. CORYNOCLADUS.*

Filaments hyaline, inarticulate, very compound, branches thicker than the trunk, clavate, without ramuli, growing from rounded or oval granular masses.

Coryncladus radiatus.—Comatose, growing in very dense bunches, occasionally straggling, branches spreading, terminal ones very long, simple, clavate, 1-150th inch long.

Length 1-100th inch, diameter of trunk 1-10000th inch, branches 1-600th in.

Habitat.—Growing profusely in the ventriculus of *Passalus cornutus*, from the mucous membrane.

NEW GENUS. CRYPTODESMA.†

Filaments ribbon-like, growing from attached granular masses. Consisting of a single cell, with a very delicate cell wall, and minute granular contents.

C. tenuis.—Filaments hyaline, compressed, attenuated at both extremities, growing in dense bunches from rounded granular masses. Cell wall very thin and delicate, granular contents of cell very fine and indistinct, measuring from 1-10000th inch to 1-6000th inch, with a few coarser granules, and occasionally a few globules, measuring 1-1875th in.

* *Coryncladus* :—*Kορινχα clava*; *κρινός*.

† *Cryptodesma* :—*Κρυπτός*, occultus; *δεσμή*, fascis.

Dimensions.—Length of filaments 1-500th to 1-75th inch; greatest breadth 1-1700th inch.

Habitat.—Grows in profusion from the mucous membrane of the ventriculus of *Passalus cornutus*.

Besides the foregoing I have found numerous free or floating entophyta in the contents, usually of the posterior part of the alimentary canal, in mammalia, aves, reptilia, pisces, mollusca, insecta, &c. These, at present, I do not feel at liberty to describe as new or peculiar, from my want of acquaintance with cryptogamic botany. A number of them, I have no doubt, if not peculiar, at least continue to grow luxuriantly in the intestinal canal; such are various *Mycoderma*, &c.; others very probably are swallowed with the food, and pass from the intestinal canal unchanged. Numerous drawings of these I exhibit to the Academy, and purpose leaving them to future investigation, or to the consideration of cryptogamic botanists, being a field well worthy of their researches. I also have a number of others, the character of which is peculiarly entophytic; but these I have not yet studied out nor figured, but hope to present descriptions of them to the Academy in a very short time.

[February. 1850. No. 50. See Bibliography.]

Dr. Leidy stated it was now eighteen months since he had sought for Entophyta within living animals, having been previously impressed with the belief of their existence upon reflecting upon the essential conditions of life. Four months since he exhibited to the Academy numerous drawings and specimens of Entophyta obtained from living animals; he now exhibited others.

The essential conditions of life are five in number, viz., a germ, nutritive matter, air, water, and heat. The four latter undoubtedly exist in the interior of living animals, animal or entozoa germs also are well known to exist, and it was rendered extremely probable that vegetable germs would also exist, and with them all the conditions necessary to vegetable growth. Plants have been very frequently observed growing upon the exterior of animals, and less frequently upon the interior, most usually upon diseased surfaces, but the growth of such parasites had not been pointed out as a normal and common condition as in the case of entozoa.

Dr. L. next reviewed the theory of generation. He inclines to the opinion that sexual elements are absolutely necessary for the perpetuation of germs. He considered the alteration of generation in certain animals no objection to the law, for after successive developments an admixture of sexual elements is observed to be neces-

sary. The reproduction among Cryptogamia may probably often exhibit phenomena analogous to the alternation of generation of animals, but universally he thinks it will be discovered that a true sexual mixture takes place in every species of these plants at some period of their life. According to the observations of Schimper, it is necessary among the mosses. From an observation made by Klencke upon a fungus which grew upon a diseased surface, Dr. L. thinks that sexual admixture would be discovered to take place in the *mycelium*. In numerous instances it had been observed among the Alge. He stated he thought he had noticed the process in *Achyla prolifera*, and gave a description of the phenomena. He finally considers that science is on the eve of demonstrating the existence of a law "that an admixture of sexual elements is necessary for the perpetuation of specific life germs."

He then exhibited numerous elaborate drawings of new entophyta observed growing in the ventriculus of *Passalus cornutus*, a remarkable one growing in a honey-like liquid in the proventriculus of the larva of *Arctia Isabella*, another from *Acheta abbreviata*, etc. He remarked that when such plants were found in animals they were usually very abundant.

Dr. L. then stated that very slight modifications in the five essential conditions of life were sufficient to produce the vast variety of living beings upon the globe. As an instance, he mentioned he had lying upon his table a saucer with a cork bottom, in which lay a partially dissected *Passalus cornutus* half immersed in water. Two days afterwards he noticed upon the part of the insect above the water a quantity of *Mucor mucedo*(?) growing, and from the part within the water numerous fine, stiff filaments, which upon examination proved to be *Achyla prolifera*; upon the cork around the insect grew a third genus, consisting of fine cottony filaments, which were articulated, of which he exhibited a drawing; and upon the insect at the surface of the water, but not within the latter, grew a fourth genus, of which he also exhibited a drawing.

He also stated that he had had the good fortune of observing in a single morning all the stages of development of *Achyla prolifera* growing from some individuals of Ascarides which had been lying in a dish of water for a few days.

In reply to some remarks made by members, Dr. Leidy said he could not admit the doctrine of spontaneous generation, but rather thought modifications in the essential conditions of life favorable to the development of different and always pre-existing germs derived from a parent.

[No. 51. See Bibliography.]

Dr. Leidy presented to the examination of the Society a colored and several other drawings of what he terms an entophytic forest, taken from a portion of the mucous membrane of the ventriculus of *Passalus cornutus*. He remarked that at least six species of Entophyta were found growing upon the mucous membrane of the ventriculus of *P. cornutus*, which were often presented in great quantity, frequently some thousands, and which from their number, polymorphous appearance of several species, and attachment to various appendages of the mucous membrane, resembled very strikingly a miniature Brazilian forest, which was heightened in some degree by the existence of a nematoid worm, which recalled to mind the idea of one of the serpents of such a forest.

A somewhat similar drawing he exhibited, taken from the small intestine of *Julus marginatus*.

Other drawings were also presented. Dr. L. stated that among his collection of living Julides, he had a number of times observed individuals to become dull in color and become almost motionless, which phenomena were followed by the death of the animal. It occurred to him that, in such a state, there might be exhibited some change in the character of its Entophyta, as usually found in the active condition of the animal. Upon removing the intestine of an individual which had just died, he noticed that the entozoa which usually occupied the small intestine, had passed into the rectum, and upon the surface of the mucous membrane of the former was developed a new plant. This is an oblate spheroidal body, white in color, translucent, embossed upon the surface, and presenting, when viewed by transmitted light, some resemblance to a minute bleached shell of an Echinus; by reflected light, it resembled a minute, white Lycoperdon. This plant was strewed all over the mucous membrane, but grew in greatest quantity along the course of filaments of Enterobrus, which appeared attached to the mucous membrane throughout their length by it. When compressed it opened, and spread into several leaf-like segments, and exuded a clear fluid with faint granules. He thought that probably this plant might be another stage in the existence of *Enterobrus*, for in the large number of individuals of *Julus* which he had examined—upwards of 130—although he had observed the development of *Enterobrus* from spore-like bodies, even to the formation of what he supposed to be the sporangia, yet he had never been able to detect the formation of spores, and when he saw this new plant enveloping the *Enterobrus* filaments he sus-

pected that there might be phenomena here presented analogous to the alternation of generation in certain animals, but had not yet satisfied himself that such was the case.

He also stated that he had discovered a fourth species of *Enterobrurus* in *Polydesmus virginiensis* and another entophyte analogous to *Enterobrurus* growing in *Polydesmus granulatus*. The latter differs from *Enterobrurus* in having numerous globular cells at the free extremity of the principal cell. He adverted to the several theories of cell formation, and said that in the last-mentioned plant in the development of the globular terminal cells the division of the permanent cell wall followed the division of the cell contents. In conclusion, he observed that these matters would be more fully treated of hereafter in a memoir which he was preparing on the subject.*

[April, 1850. No. 54. See Bibliography.]

DESCRIPTION OF NEW ENTOPHYTA GROWING WITHIN ANIMALS.

Eccrina† (Gen. Nov.).—Characters same as *Enterobryrus*,‡ except that it divides into numerous cells at the free extremity.

Eccrina longa.—Filaments long and delicate, hyaline, or faintly brownish, at first forming a simple curve or a single spiral turn and then passing in a straight line to the free extremity. Peduncle very short. Frond cell usually filled with globules, and a few granules, except at free end, where it is usually filled with granules, to the exclusion of the globules. End cells as high as thirty in number, at first consisting of elongated divisions of the frond cell contents, but becoming distinct elliptical cells from two to three times longer than the breadth; contents usually granular, occasionally with a few globules. End cells finally separating from the parent. Length from three to seven lines; breadth 1-2000th to 1-517th inch, not usually corresponding to the length. End cells 1-517th to 1-357th inch in length.

Habitat.—Grows in very great profusion from the mucous membrane of the posterior part of the intestine of *Polydesmus virginensis*.

(Dr. L. exhibited to the Academy a preserved fragment of mucous membrane, with filaments of this species six lines in length growing from it.)

* No. 131. See Bibliography.

† *Eccrina*: *Eccrina* segregata.

‡ Proc. Acad., Oct. 9, 1849.

Ecrina moniliforma.—Filaments hyaline or yellowish, forming a double or treble spiral. Peduncle short. Frond cell filled with globules and granules, except toward its free extremity, where it is filled with granular matter divided into distinct and separate masses, usually a little shorter than broad, and containing each a globular nucleolated nucleus. Divisions progressively passing towards the end into globular cells with granular contents. Divisions and globular cells from 20 to 50 in number.

Length from 1 to $1\frac{1}{2}$ lines, breadth average 1-1500th inch. Divisions of frond cell contents and globular cells from 1-1875th to 1-1500th inch. Nucleus of cells 1-3750th inch.

Habitat.—Grows in moderate quantity from the mucous membrane of the intestine of 50 per cent of *Polydesmus granulatus*.

Arthromitus nitidus.—Filaments very long, hyaline, grows usually in twos or fours, pointed at the origin, rounded at the termination. Articuli very distinct, length equal to the breadth of the filament. Sporuli formed within the articuli, solitary, usually oblique, oval, amorphous.

Length 1 line by 1-5000th inch broad. Spores 1-7.111th inch long by 1-12.500th inch broad.

Habitat.—Grows in considerable quantity with a profusion of young *Enterobryus elegans* from the mucous membrane of the posterior portion of the rectum of *Julus marginatus*.

Remarks.—Since I established the genus *Arthromitus** I have observed the formation of its sporuli. These originate in the amorphous matter of the articuli, apparently by a very gradual aggregation and condensation of the contents. They are always single and usually lie oblique, and frequently alternate with each other in this position in the different articuli. When they first appear they are larger than when fully formed, are frequently bent, or clavate in form, and very indistinct, but as they ripen they become more regular, oval, distinct, and quite refractile of light. Usually they are observed at the extremity of the filaments only, but frequently they are found existing in the whole length of the latter.

A species of *Arthromitus*, and also of *Cladophytum* is found in the intestine of *Polydesmus virginianus*.

The *Higrococci intestinalis*, found by Valentin in the *Blatta orientalis*, I could not find in our domestic cockroach, although I found numerous simple, phytid, inarticulate filaments, growing from an oxyuris infesting this animal.

* Proc. Acad., Oct. 9, 1849.

[October, 1850. No. 56. See Bibliography.]

CONTRIBUTIONS TO HELMINTHOLOGY.

1. *Ligula Tritonis*.—Body ribbon like, thin, translucent, nearly smooth, faintly yellowish white, posteriorly obtusely rounded. Head thickened, rounded, transversely corrugated, yellowish. Extremity triangularly rounded, laterally compressed, front and back, with a short, longitudinal, contracted depression.

Whole length 1 inch 9 lines; breadth of body 1-3d line; thickness 1-12th line; length of head 1 line; breadth 1-4th line; thickness 1-9th line.

Habitation and Remarks.—This species was sent to me by my friend, Prof. S. F. Baird, of Carlisle, with the note "Found embedded in the muscles of the back of *Triton (Cynops) dorsalis*." It is the smallest species which has as yet been discovered, and the first among batrachian reptilia. The specimen sent to me consisted of two fragments of the same individual preserved in alcohol. Examined beneath the microscope it presented no trace of articulation or interior definite organs.

2. *Pentastomum Didelphidis Virginianae*.—Body subcylindrical, curved one-third or one-half a circle, dorsum convex, ventrum concave, posteriorly narrowed and constricted a short distance from the extremity, which is rounded. Color white, opaque. Composed of forty or fewer annulations. Head posteriorly convex, anteriorly plain or slightly concave; mouth nearly round; hooks simple, situated in a curved line of which the mouth forms the center.

Whole length 3 to 5 lines; breadth 3-5ths of a line; annuli generally 1-80th inch wide; mouth 1-200th inch in diameter; hooks 1-200th inch long.

Habitation and Remarks.—I found 9 individuals of this entozoon in C-shaped cysts, the circle being 2 lines in diameter, imbedded in the liver just beneath the peritoneal surface in *Didelphis virginiana*. It may probably be the *Pentastomum subcylindricum* of Diesing,* which was found in cysts upon the liver of two South American species of *Didelphis* and several other animals; but the largest of those found in our *D. virginiana* is equal to the smallest of *P. subcylindricum*, and has not more than one-half the number of annulations.

3. *Pentastomum euryzonus*, Diesing.

* Annal. d. Wien. Mus. 1, p. 21. Dujardin: Hist. Nat. des Helmintes, p. 305. Diesing: Systema Helminthum, vol. I, p. 611.

Linguatula Diesingii, Van Beneden. ; Bull. de l'Acad. Roy. des Sc. de Brux., 1848 ; Mem. de l'Acad. de Brux. XV. An. Sc. Nat. 3 ser. XI.

Pentastomum curyzonum, Dies. Syst. Helminth.

Body cylindriod fusiform, curved, posteriorly subacute. Color yellowish white, opaque. Annulations under 20, with wide intervals. Head plano-convex; mouth round.

Whole length 6 lines; breadth anteriorly 1 line of antepenultimate annulus 3-5ths of a line. Mouth 1-40th of an inch.

Habitation.—I found five individuals of this species, enclosed in C-shaped cysts, upon the surface of the liver beneath the peritoneum, in a half-grown *Cynocephalus porcarius*.

4. *Pentastomum Proboscideum*, Rud.

Echinorhynchus Crotali, Humboldt. Ansicht d. Natur. 1 Auf.

Distoma Crotali, ib. ; Rud. Entoz. hist. II.

Poroccephalus Crotali, Humb. Recueil d'Obs. de Zool.

Polystoma proboscideum, Rud. Mag. d. Berl. Gesell. Nat. Fr. VI.

Linguatula proboscidea, Van Beneden, Mem. de l'Acad. de Brux. XV.

Linguatula clavata, Wyman. Jour., Bost., Nat. Hist. Soc. Vol. V.

Pentastomum proboscideum, Rud. Synop. ; Humb. Ans. d. Nat. Bremser, Icones ; Diesing, An. d. Wien. Mus. ; Syst. Helminth. I.

Body sub-clavate, broadest anteriorly, recurved, posteriorly dilated ovate, subacute. Color yellowish white; integument translucent. Annulations 36, becoming indistinct toward the extremities. Head round, mouth round. Male furnished with two short projecting papillæ just above the mouth; penis papillaform, projecting 1-4th of a line.

Length of female $2\frac{1}{2}$ to $3\frac{1}{2}$ inches; breadth of head $2\frac{1}{2}$ lines; narrowest part of body 1 line, just anterior to posterior dilatation, which latter is 3 lines long by $1\frac{1}{2}$ broad. Length of male 1 inch 3 lines to 1 inch 5 lines; breadth of head $1\frac{1}{2}$ lines; narrowest part of body $\frac{1}{2}$ line; breadth of posterior dilatation 3-5th of a line.

Habitation and Remarks.—I found six females, four males, and a young individual of this species $4\frac{1}{2}$ lines long in the pulmonary cavity of a boaconstrictor. The form of the body in the male and female is the same.

5. *Echinorhynchus Ovatus*.—Body compressed ovate, posteriorly subacute, cured, yellowish white, opaque, presenting 12 to 14 transverse corrugations; neck distinct, short, cylindrical. Proboscis globular, armed with six rows of recurved hooklets.

Length 2 lines; greatest breadth 1-10th inch; greatest thickness 3-5th line. Proboscis $\frac{1}{4}$ line.

Habitation.—Two individuals were found in the iliac portion of the small intestine of *Felis leopardis*.

6. *Echinorhynchus Tortuosus*.—Body brownish white, opaque, very much contorted and transversely corrugated, subcompressed, dilated just below the middle, attenuated towards the extremities, most so anteriorly, posteriorly recurved and obtuse. Neck short. Head subglobular, armed with four rows of simple recurved hooklets.

Length 2 inches 8 lines; greatest breadth 1-7th inch; greatest thickness 1 line; diameter 1 line from the neck 1-5th of a line; from the posterior extremity 4-5ths of a line. Proboscis and neck 1-5th line long.

Habitation.—Found with the anterior 3 lines of its length buried in an oval tumor 4 lines in diameter in the mesentery of a *Didelphis virginiana*.

7. *Echinorhynchus Pici collaris*.—Body white, opaque, sub-cylindrical, sub-compressed, and curved posteriorly; transversely corrugated and slightly so longitudinally, moderately dilated anteriorly. Neck very short. Proboscis short, cylindrical, contracted in the middle, with the free extremity rounded and furnished with four rows of simple recurved hooklets.

Length 1 inch 8 lines; breadth anteriorly 1-10th inch; thickness 1-12th inch; posteriorly 4-5ths line broad by 3-5ths line thick. Proboscis 4-5th line long: thickness $\frac{1}{2}$ line.

Habitation.—Intestine of *Picus collaris*.

Remarks.—Differs from the *E. Pici*, Goeze,* which has a long linear proboscis, with 8 or 10 ranges of hooklets, and is narrower in front than behind, just the reverse of the species just described.

[October, 1850. No. 57. See Bibliography.]

NOTES ON THE DEVELOPMENT OF THE GORDIUS AQUATICUS.

Just four years ago I exhibited to the Academy a mass of living hair-worms or *Gordius aquaticus*, consisting of fourteen individuals strangely knotted together, and recalling the appropriateness of the Linnean name.

It is a vulgar opinion that the *Gordius* is a horse hair which has become vivified from maceration for several weeks in a spring or pool of fresh water, an error which has probably arisen from their

* *Naturgeschichte S. 151, Taf., 11.*

frequently being found in water filling a wagon rut or the drinking trough of a horse. I have even been informed by some persons, though by those not given to observe such matters, that they had perceived the direct transmutation of horse hairs into writhing worms, and I was at one time so silly as to be led to try the experiment, with what success it is unnecessary for me to state.

The Gordii alluded to in the mass were blackish brown in color, from 6 to 10 inches in length, and most of them had attached to the posterior extremity of the body a long, white, opaque cord, in several instances nearly as long and as thick as the worms themselves. These cords, some of the members may recollect, I pointed out at the time as being strings of the ova of the Gordii, but I then was not so well acquainted with the history of the *Gordius* as at present—that is to say, I did not know that we have no knowledge whatever of its origin or development—and although through curiosity I traced for a few days the development of the embryo in ova, yet I did not do it with that care which its importance demanded. But however imperfect have been the observations made with this acknowledgment, I have thought it would be well to record them with the hope that they may not only throw some light upon the obscure nature of the *Gordius*, but also lead others to the discovery of a similar opportunity of investigating this animal under more favorable circumstances of locality and information. The observations I have withheld for a length of time in the hope that I might be able to verify or correct them, but failing to do so to the present time I now reluctantly put them forth from my notes taken at the time.

The white cords before mentioned consisted of numerous oval ova closely aggregated together. These when examined beneath the microscope on the first day after I obtained them exhibited a white granular yolk divided into four globular masses connected together and surrounded by a transparent albumen. Each mass contained in its center a clear cell or vesicle. On the second day the separation among the yolk masses was less distinct, and upon the third day the whole had united into one oval, finely granular body, and the interior vesicles had disappeared. The fourth and fifth days no perceptible change was observable. From the sixth to the eighth day the yolk had become conical in form, and upon the ninth day the base of the cone exhibited a cleft or fissure which by the tenth day had extended two-thirds the length of the mass. During the whole of this period the yolk retained its granular character and was motionless. Upon the eleventh day it resembled a cylinder doubled upon itself, or the outline of the embryo had been formed, and one ex-

tremity of it, corresponding to the head, had become translucent from a solution of the granular matter within. The other or tail end was subacute. The twelfth day the translucency had extended itself to the interior part of the embryo, the extremity of which had advanced beyond the others and presented an emargination communicating with an orifice opening into a canal visible in the interior, and from the edge of the extremity was developed a circle of short filaments which projected downwards and outwards. From the thirteenth to the fifteenth days the granular matter had entirely undergone a solution within the anterior half of the embryo, and the latter had become somewhat dilated. The interior canal was also more distinct, and the bordering filaments of the extremity were larger. In the course of the sixteenth to the eighteenth day the translucent half of the animal was separated from the other by a constriction, and the canal in the interior presented at its anterior portion a clavate tubular body, the free end of which projected from the oral aperture. The extremity of the head was surrounded by a reflected collar, from the free border of which projected the filamentary appendages. The posterior half of the embryo was still granular in appearance, but had become rounded and somewhat dilated at the extremity. From the nineteenth to the twentieth day the embryo alternately retracted and protruded the tentacular or filamentary appendages, and the integument of the anterior half of the body appeared to be getting annulated, which was distinctly so by the twenty-first day. The granular matter in the posterior part of the body was also undergoing solution from the periphery towards the center, and at its posterior part there appeared several large oil globules. On the twenty-second day the annulations of the anterior half of the body were very distinct, the posterior half was also becoming annulated, and near its extremity I for the first time observed an anal orifice and one to four small epidermal spines. On the twenty-fourth day the tubular clavate organ before mentioned, occupying the anterior part of the alimentary canal, was alternately protruded and retracted as a proboscis. The proboscis, when fully protruded, brought into view at its base a second circle of tentacular filaments within the first. On the twenty-sixth day the embryo, when pressed from the egg, progressed forward by moving the posterior half of its body from side to side, and it alternately protruded and retracted the proboscis and the two circles of tentacular filaments. When all the latter organs were retracted the head presented a truncate or depressed surface, and in their protrusion the extremities of the outer circle of tentaculae and the end of the pro-

proboscis first became visible; as these advanced the second circle of tentaculae appeared, and when the proboscis was entirely protruded the outer tentaculae were deeply reflected upon the outside of the body, and the inner circle projected obliquely outward and upward. The proboscis was clavate in form or cylindrical and moderately dilated at its free end, and more so at its base. The following six days no perceptible change was observable in the development of the animal, and after this the egg showed evident appearances of decay, and I gave them no further attention.

[No. 58. See Bibliography.]

TWO NEW SPECIES OF INFUSORIAL ENTOZOA.

1. *Nyctotherus Ovalis*.—Body translucent oval, posteriorly obtuse. Anterior granular areola three sided. Posterior fissure passing downward.

Length 1-100th inch; breadth 1-33d inch (error).*

Habitation.—The intestinum tenue of the *Blatta orientalis*, occasionally in considerable numbers.

2. *Bodo Julidis*.—Body translucent, faintly greenish, faintly granular, with one or two large round vacuolæ and numerous minute ones; form changing, usually globular, oval, or pyriform. Caudæ twice the length of the body; very active, frequently twisted into a ring at the extremity. Diameter of body 1-3000th inch.

Habitation.—The large intestine of *Julus marginatus*, in company with *Nyctotherus velox*, often in millions.

[No. 59. See Bibliography.]

DESCRIPTION OF SOME NEMATOID ENTOZOA INFESTING INSECTS.

Genus *Aorurus*. Sub-genus *Streptostoma*. Proc. Acad. Nat. Sci., 1849, p. 230.

1. *Streptostoma gracile*.

Oxyuris Diesingii. Hammerschmidt. Isis von Oken J. 1838, S. 354, Taf. iv, Fig. 6.

Body attenuated from the middle anteriorly and posteriorly, white, translucent, shining. Anterior annuli very broad and movable upon one another. Oral annulus short, truncate; second

* Length 1-187th inch; breadth 1-250th inch. See "Some Observations on *Nematoidea imperfecta*," Trans. Amer. Philosoph. Soc., 1853, p. 244 (with drawing).

annulus long, constricted in the middle. Tail nearly one-third the length of the body, shining, straight or curved. Pharynx short. Oesophagus consisting of two elongated, pyriform, muscular bulbs. Neck of first oesophageal bulb dilated at commencement and middle; neck of second long, narrow, and cylindrical. Ventriculus largely dilated and oval at commencement, afterwards cylindrical.

Length of body 1 line; breadth opposite ventricular dilatation 1-136th inch; just above anus 1-300th inch; greatest do. 1-107th inch; length of tail 1-40th inch; breadth at middle 1-1360th inch; length of first pyriform bulb of oesophagus 1-150th inch; breadth of neck do. 1-1100th inch; do. of body of do. 1-400th inch; length of second bulb 1-214th inch; breadth of neck 1-1300th inch; do. of body 1-340th inch; do. of dilated commencement of ventriculus 1-214th inch; do. of cylindrical portion 1-330th inch.

Ova oval, 1-300th inch long by 1-625th inch broad.

Habitation.—Found in numbers of one to half a dozen in the small intestine of our domestic cockroach (*Blatta orientalis*). This species was discovered by Hammerschmidt, who named it *Oxyuris diesingii*, but as it is considered a doubtful compliment to name intestinal worms after persons, in placing it in the genus *Streptostoma*, I have also changed the specific name. The individuals from which my description is taken were the largest I found.

Sub-genus *Thelastoma*. Proc. Acad. Nat. Sci., 1849, p. 231.

2. *Thelastoma appendiculatum*.—Body cylindrical, narrowed anteriorly and posteriorly, white, translucent, shining, strongly annulated. First division of the oesophagus moderately long, cylindrical; second portion short, broad, and pyriform, ventriculus dilated cordiform at commencement, becoming rapidly narrowed and cylindrical, and sending off posteriorly a large and long pyriform diverticulum or coecum, afterward cylindrical to termination, and forming a single short convolution just posterior to the generative aperture. Tail straight, spiculate, one-fourth the length of the body. Eighty-five annulations to the body, of which there are twenty-eight from the mouth to the commencement of the ventriculus. Generative aperture twenty-six annulations from the anal aperture. Last annulation furnished with two short spines projecting backward.

Length of body 1 line to 1-10th of an inch; breadth at ventricular commencement 1-100th inch, at middle 1-80th inch, at anus 1-160th inch; tail 1-50th inch long, breadth at middle 1-888th inch; first portion of oesophagus 1-80th inch long, 1-533d inch broad; second portion 1-240th inch long; neck of do. 1-666th inch broad, body of do. 1-250th inch; commencement of ventriculus 1-200th inch broad;

cylindrical portion 1-400th inch; diverticulum of ventriculus 1-66th inch long by 1-266th inch broad.

Ovum semi-oval, 1-258th inch long by 1-666th broad.

Habitation.—Found in the intestinum tenue of the domestic cockroach (*Blatta orientalis*), with the former.

3. *Thelastoma Labiatum*.—Body white, translucent, anteriorly strongly annulated. Papilla of the mouth dilated, six lobed. First portion of œsophagus cylindrical, second portion broad, pyriform; ventriculus sub-cordiform at commencement. One hundred and fifty annulations, of which there are forty from the mouth to the commencement of the ventriculus.

Length of body 1-22d inch; greatest breadth 1-200th inch; length of tail 1-40th inch; length of first portion of œsophagus 1-120th inch; breadth 1-1000th inch; second portion 1-320th inch long by 1-400th broad; breadth of ventricular dilatation 1-266th inch.

Ovum oval, 1-333d inch long by 1-500th inch broad.

Habitation.—Found in numbers of from one to a dozen in the intestine of *Polydesmus virginicensis*.

4. *Thelastoma Robustum*.—Body white, cylindrical, narrowed anteriorly and posteriorly. First portion of œsophagus long, cylindrical, second portion broad, pyriform. Commencement of ventriculus dilated, oval, afterwards cylindrical. Articulations of body 212, of which there are forty from the mouth to the commencement of the ventriculus, 102 from the latter to the generative aperture, and from this to tail 70.

Length of body 2 lines; breadth at ventricular dilatation 1-75th inch; at sixth annulation from mouth only 1-320th inch; at middle 1-66th inch; just above anus 1-75th inch; tail 1-22d inch long by 1-1000th inch broad; at middle, first portion of œsophagus, 1-50th inch long by 1-500th inch broad; second portion 1-178th inch long by 1-200th inch broad; ventricular dilatation 1-105th inch broad.

Ovum oval, 1-308th inch long by 1-500th inch broad.

Habitation.—Found in the intestine, in numbers of from one to three, in the larva of a lamellicorn insect.

Remark.—The descriptions of the above are entirely taken from females, considerable numbers of which I have found and possess, but I have never yet been able to discover a single male.

5. *Oxyuris Socialis*.—Body white, narrow, cylindrical, elastic, posteriorly attenuated; mouth projecting, with a short pharynx; œsophagus consisting of two portions; first portion long, cylindrical, dilated at the posterior part; second portion narrow, pyriform,

ventriculus moderately dilated at commencement, capacious, cylindrical; tail long, narrow, acute.

Female.—From 1 line to 2 and 1-5th lines in length; breadth 1-266th inch; first portion of oesophagus 1-66th inch long, 1-800th inch broad; second portion 1-200th inch long by 1-666th inch broad; generative aperture projecting, just anterior to the middle; tail simple pointed, 1-57th inch long from anus, 1-400th inch broad at base.

Ovum oval, white, 1-363d inch long, 1-666th inch broad.

Male.—Length 4-5ths to 3-5ths of a line; breadth 1-400th incl; posteriorly recurved; tail pointed, furnished with five minute epidermoid prominences on the inner side, 1-133d inch long from anus; spiculum of penis single, simple, curved, 1-400th inch long.

Habitation.—Found in numbers of from five to twenty, of which one-fifth are males, in the large intestine of the large black cricket (*Acheta abbreviata*).

Genus Hystrignathus.—Body cylindrical, anteriorly furnished with transverse rows of simple spines projecting backward; mouth surmounting a large naked papilla; cesophagus of two portions; the first long, cylindrical, the second short and pyriform; annulations indistinct posteriorly; tail long.

6. *Hystrignathus Rigidus*.—Body straight, rigid, cylindrical, narrowed anteriorly and posteriorly, anteriorly furnished with 106 transverse rows of simple spines projecting obliquely backward, each row corresponding to an annulation and containing about sixteen spines; anterior spines longest, equal to the width of the annulations, becoming shorter posteriorly and decreasing to mere points; first annulation of the mouth truncated, conical, smooth; second annulation smooth; pharynx extending through the first two annulations; first portion of oesophagus long, cylindrical; second portion with a narrow cylindrical neck and globular body; ventriculus cylindrical, slightly dilated anteriorly, narrowed anteriorly; rectum elongated, conical; tail long, curved; generative aperture very near the middle of the body.

Length 2 lines; greatest breadth 1-140th inch; tail 1-40th inch long from anus, 1-100th inch broad at middle; anterior or spinous portion of body 1-26th inch long or one-fourth of the whole length. First portion of oesophagus 1-50th inch long, 1-520th inch broad; second portion 1-190th inch long, 1-320th inch broad at body. Anterior spines 1-2000th inch long. Fifty-eight spinous annulations corresponding to the first portion of the oesophagus, twelve to the second portion. Annuli posteriorly indistinct.

Ova oval, 1-214th inch long by 1-545th inch broad.

Habitation.—The female only I have found in numbers of one to five within and adhering by the mouth to the parietes of the ventriculus of *Passalus cornutus*.

[November, 1850. No. 60. See Bibliography.]

DESCRIPTION OF THREE FILARIÆ.

1. *Filaria Hominis oris*.—Body white, opaque, linear, thread-like. Mouth round, simple. Posterior extremity obtuse, furnished with a short, curved, epidermal hooklet 1-500th inch in length by 1-2000th inch in diameter at base.

Length 5 inches 7 lines; greatest breadth 1-66th inch; breadth at mouth 1-250th inch, at posterior extremity 1-80th inch.

Remarks.—The description is taken from a single specimen preserved in alcohol in the collection of the Academy, labelled, "Obtained from the mouth of a child."

Is it a young individual, or perhaps a male of the *Filaria medinensis* or Guinea worm? The latter, as it is well known, infests the human body, often growing to an enormous length, several yards or more, in the inter-tropics of Asia and Africa. It is frequently brought in the body of negro slaves from Africa to America, where no entozoon of the kind has ever been noticed to be parasitic in man as an indigenous production. From some late observations on the course of life of entozoa, helminthologists have been led to suspect that most, and probably all, entozoa pass different stages of their existence in different animals. If such be the fact, may the *Filaria medinensis* not owe its introduction into the human body from the custom which prevails in those countries where the worm is found of using insect food? Insects are well known to be infested with Filariae, probably more than any other class of animals. In Egypt, Arabia, &c., the locust is eaten, in Guinea, &c., the larger coleoptera, in the raw state, and in this condition Filariae may often be swallowed, and reach a higher development of their existence in the human body.

2. *Filaria Canis cordis*.—Body white, opaque, linear, nearly uniform throughout, posteriorly subulate, pointed; mouth simple, round.

Length 10 to 10½ inches, greatest breadth 2-5ths of a line, anteriorly 1-5th of a line; half an inch from posterior end, 1-10th of a line.

Remarks.—The description is taken from two individuals preserved in alcohol, in the collection of the Academy, presented by Dr. R. Coates, who obtained them, according to the label upon the bottle, from the parieties of the heart of a dog.

3. *Filaria Boæ constrictoris.*

Body white, cylindrical; integument translucent, longitudinally straited, mouth simple, round; œsophagus cylindrical, opaque, white; intestine opalescent, cylindrical, tortuous, corrugated, wider than the œsophagus; anus terminal, round; generative aperture close to the mouth; ovaries two, very long and very tortuous.

Remarks.—The description is taken from two specimens; one 10 inches long by 4-5ths of a line wide, the other 6½ inches long by 3-5ths of an inch wide. In the former the œsophagus is 9 inches long and 1-3d of a line wide, the intestine 13 inches long and 3-5ths of a line wide.

Habitation.—Found in the areolar tissue, in an irregular or tortuous position, between the muscles of the ribs and the integument of a Boa constrictor.

NOTE.—In the same Boa constrictor, which was dissected by my friend Dr. Hallowell and myself, we found in the right lung 6 females, 4 males, and a very young individual of *Pentastomum proboscideum*, and in the ureters of the kidneys 26 individuals of *Distomum horridum*.

[December, 1850. No. 64. See Bibliography.]

DESCRIPTION OF NEW GENERA OF VERMES.

Peloscolex. n. g.—Setæ in two rows, 6 to 10 in each fasciculus; podal hooks in two rows, in twos or threes, bifurcated at the free extremity, each annulation furnished with a circle of prominent tubercles, with numerous smaller ones. Upper lip hardly projecting. Girdle not prominent. Blood red.

1. *Peloscolex Variegatus.*—Body cylindrical, posteriorly obtuse, anteriorly sub-acute. Setæ simple, usually 10 in each fasciculus anterior to the girdle, absent in the posterior 22 annulations. Podal hooks anteriorly in threes, divergent, strong, sigmoid, bifurcated at the extremity; posteriorly in twos, one rudimentary. Each annulation furnished with a circlet of elevated, rounded tubercles, 1-8ooth inch in height, and numerous smaller ones, also arranged in transverse circles. Anterior 3 or 4 annulations reddish; after these 25 are deep black, except the 10th or girdle, which is broad

and brownish; posterior annulations red or brown. Upper lip so little projecting that mouth appears almost terminal, furnished with short, stiff hairs. Whole number of annulations 50.

Length 4 lines; length of setæ 1-133d inch to 1-80th inch; length of podal hooks 1-400th inch to 1-178th inch.

Habitation.—Found in the spring of the year in the ferruginous mud at the bottom of springs impregnated with iron, near Philadelphia.

2. *Chaetogaster*, Baér :

Baér, Nova acta nat. Curios., 1827, p. 614; Ehrenberg, Symb. Phys., 1831, *Nais diaphina* and *Nais diastropha*. Gruithuisen. Nov. act. nat. cur., 1828, p. 407.

Body cylindrical, elongate; mouth inferior, large, triangular; anus terminal. Podal spines in transverse fasciculi, inferior, simple; the first pair of fasciculi close to the mouth; the second distant. Intestine straight, capacious. Eyes none. Blood white. Increasing by division. Leidy.

2. *Chaetogaster Gulosus*.—Body whitish, translucent; posteriorly obtuse, ciliated with long hairs; mouth infero-terminal, large, triangular, simple, upper lip digitiform, ciliated. Oesophagus short, narrow; first stomach long, cylindrical, transparent; second stomach large, oblong; intestine straight, capacious. Podal spines in pairs of fasciculi of 5 or 6 each, simple, divergent, curved backward near the free end, retractile; first pair just posterior to each side of the mouth inferiorly; second pair removed far back. Usually found in the state of division; commonly 2 to 4 subdivisions.

First subdivision 1-24th inch, furnished with 6 pairs of fasciculi of podal spines; the second pair one-half the length of the subdivision from the first or oral pair. Second subdivision 1-100th inch; third 1-66th inch; fourth 1-100th inch. Each of these latter furnished with 4 fasciculi of podal spines.

Whole length 1 line, will contract to half a line; breadth 1-140th inch; mouth, when open, 1-250th inch; length of podal spines 1-133d inch.

Habitation and Remarks.—Found abundantly with *Hydra fusca*, etc., in the water of marshes in the vicinity of Philadelphia. This worm is very active in its movements and very rapacious. Creeping upon bodies in the water, it rapidly elongates the anterior part of its body in various directions, and swallows great numbers of the smaller infusoria. In turn it is much preyed upon by the *Hydra fusca*. When the anterior part of the body is elongated in search of food the mouth is much distended and terminal.

3. *Rhynchoscolex*, n. g.—Body cylindrical, soft, naked, transversely and finely striated, vibrillated, anteriorly elongated into a proboscidiform appendage. Mouth inferior; anus terminal. Intestine simple, straight. Eyes none.

3. *Rhynchoscolex Simplex*.—Yellowish white, opaque, anteriorly abruptly attenuated into a long, cylindrical, clavate proboscidiform appendage; anteriorly abruptly narrowed, obtusely truncate or rounded. Proboscis presenting longitudinal and numerous transverse marks. Mouth inferior, at the base of the latter appendage. Intestine straight and capacious.

Length 2 to 3 lines; breadth 1-6th of a line: proboscis 1-13 $\frac{1}{3}$ d inch long, but may lengthen to 1-80th incl.

Habitation and Remarks.—A small wriggling worm found among yellowish fragments of vegetable matters and conservae at the bottom of clear brooks in the vicinity of Philadelphia. Under a very little pressure it undergoes rapid disintegration into globular masses (cells of the structure distended by endosmosis?).

1. *Emea**.—Body elongated, plano-convex, soft, proteiform, naked, covered with minute vibrillæ. Alimentary canal simple, tortuous, furnished with a gizzard containing a dental apparatus. Mouth and anus terminal. Eyes two or three, on each side of head.

1. *Emea Rubra*.—Elongated, compressed, contracting irregularly, broadest posteriorly, anteriorly obtuse, yellowish flesh colored. Head semi-oval, neck projecting laterally. Eyes, two or three black spots placed in a line behind one another on each side of the head and neck. Mouth simple, opening into a narrow pharynx. Intestine cylindrical, narrowed posteriorly, furnished with a small, round, muscular stomach containing a corneous dental apparatus at its entrance. Generative apparatus consisting of two very tortuous and capacious tubes, passing the whole length of the body on each side of the alimentary canal.

Length from 3 to 10 lines; breadth 1-5th to 1-3d of a line.

Habitation and remarks.—Found in marshes in the vicinity of Philadelphia, creeping upon dead vegetable substances or upon the ground. When touched or irritated it secretes a large quantity of very tenacious mucus. Under slight pressure it will voluntarily evert more than one-half of the intestinal canal through the mouth, and, upon removal of the pressure, after some minutes will again

* *Emea*: ἐμεά, from the disposition the animal has to protrude or vomit forth the anterior part of the intestine.

withdraw it, and apparently without any injury having been sustained, as the animal lives for days afterwards in its usual circumstances. The interior of the body, in the intervals of the viscera, is filled with discoidal corpuscles, as in *Nais*, etc. The interior of the intestine is everywhere furnished with nutritive villoid appendages.

2. *Anortha*.*—Body sub-compressed, soft, naked, vibrillated, inarticulate. Alimentary canal simple, straight, alternately contracted and dilated. Mouth and anus terminal, simple, indistinct. Eyes, none.

2. *Anortha Gracilis*.—White, opalescent, very contractile, moniliiform from an alternation of contraction and dilation, corresponding usually to ten segments, into which the animal may be subdivided, but more or less disappearing elongation of the body, becoming more apparent by wrinkling in shortening of the body : anteriorly semi-ovate, subacute ; posteriorly elongated, cylindroid, obtusely rounded. Apparent segments panduriform, furnished each posteriorly with a clear globular nucleolated nucleus. Intestine variable in capacity, usually dilated in the anterior dilatation of each apparent segment, and much contracted in the intervals.

Length from 1 to 2 lines, shortening 1 or 1-4th of a line ; breadth when elongated from 1-400th to 1-300th inch ; when shortened from 1-300th inch to $\frac{1}{2}$ of a line.

Habitation and Remarks.—Found in the same situation as the preceding, creeping planaria-like upon different substances, or most frequently holding a vertical position in the water, apparently without movement, but retaining their position by means of the actively moving vibrillæ, which are comparatively larger than in the preceding worms. They appear to feed upon vegetable particles brought to the mouth by means of the currents produced by the vibrillæ. The intestine is usually empty, except at the dilated portions, where it is yellowish or greenish, from granular matters contained within. The whole structure of the animal is exceedingly simple, composed of nucleolated, granular corpuscles, those forming the exterior of the body being furnished with vibrillæ. Under slight pressure these corpuscles undergo separation from one another and become globular by endosmosis. In this state they measure from 1-700th inch to 1-2800th inch. The nucleoli are globular, shining, and measure 1-900th inch in diameter. The exterior vibrillated corpuscles, after separating from the body, often move about for some seconds. The

* *Anortha* : ανωρά, from the erect position of the animal.

vibrillæ measure about 1-3500th inch long. Each segment of the animal's body at its posterior part contains a globular transparent nucleus measuring 1-2333d inch in diameter, with a globular, refractile nucleolus 1-7000th inch in diameter. This latter body, with the form of the apparent segments, makes the animal resemble a row of gregarinæ attached together.

[February, 1851. No. 70. See Bibliography.]

DESCRIPTION OF A NEW SPECIES OF ENTOZOA.

1. *Cuculanus Roseus*.—Body rose-red with whitish tips, translucent, cylindrical, robust, narrowed at the extremities; anteriorly obtuse; posteriorly acute. Mouth elongated, surrounded by a papillated lip, and enclosing a complex, corneous, yellow-colored apparatus. Oesophagus consisting of two portions—the first long, cylindrical; the second short, narrow, pyriform. Ventriculus broad, cylindrical. Anus very near the posterior end. Tail 1-5th of a line long.

Female.—Length 1 inch to $1\frac{1}{2}$ inches; breadth 3-5ths of a line. Generative aperture 4 lines from end of the tail. Ovaries two, white, very tortuous.

Male.—Length 6 to 10 lines; breadth $\frac{1}{2}$ line. Penis composed of two, white curved, spiculae, 4-5ths a line long, protruding close to the anal aperture.

Habitation.—I found 580 adult specimens and many thousand young of this species in the intestine of a Tortoise (*Testudo* — ?) from Java. About one-fourth of the number were males.

2. *Ascaris Felis discoloris*.—Body yellowish white, subcylindrical, with prominent longitudinal lines; posteriorly acute; anteriorly moderately narrowed with the extremity furnished with a narrow lateral alaform expansion undulated at the free edge. Mouth distinctly trilobed. Tail short; anus just anterior to the point of the latter.

Length 1 inch to $1\frac{1}{2}$ inches; greatest breadth at the posterior third $\frac{1}{2}$ a line; posterior to alaform expansion $\frac{1}{4}$ of a line; length of latter 1 line; greatest breadth at base 1-10th of a line. Annulations 1-570th inch wide.

Habitation.—Six females obtained from small intestine of *Felis discolor*.

3. *Spiroptera Didelphidis virginianæ*.—Body whitish, cylindrical; anteriorly narrowed, sub-acute; posteriorly curved, acute, furnished

with a broad, inflated, lateral, alaform expansion of the integument, pierced on each side of the body with five minute respiratory tubes opening at the free edge of the expansion. Integument on the ventral surface, between the lateral expansions, presenting a number of elevated, longitudinal, moderately tortuous, papillated, linear ridges. Mouth small, round. Oesophagus long, cylindrical. Intestine simple, tortuous. Anus small, oval, situated about half the length of the alary expansion, from the posterior end.

Length 11 lines; breadth 3-5ths of a line. Transverse striae of integument 1-650th inch wide. Oesophagus $2\frac{1}{2}$ lines long, 1-5th of a line broad.

Habitation.—The description is taken from two males found within the stomach of *Didelphis virginiana*.

4. *Spiroptera Scalops canadensis*.—Body whitish, cylindrical; anteriorly attenuated; posteriorly re-curved; furnished at the extremity with a lateral dilated alary expansion, containing four minute respiratory tubes, diverging from the position of the anus. Mouth small. Oesophagus cylindrical; intestine moderately tortuous. Anus about half the length of the alary expansion from the posterior end.

Length 6 lines; breadth $\frac{1}{4}$ of a line. Oesophagus $\frac{1}{4}$ of a line long.

Habitation.—Description from a single male found in the stomach of *Scalops canadensis*.

5. *Echinorynchus socialis*.—Body white, cylindrical, with a dilation of the anterior fifth; narrowed posteriorly, with a white spiral band passing around the whole length, and giving the appearance of transverse annulations. Proboscis moderately long, cylindrical, with twenty-six transverse rows of simple re-curved hooklets, sixteen in each row.

Male furnished with a posterior vesicular appendage.

Length from $\frac{1}{2}$ an inch to 2 inches 4 lines; breadth of larger individuals anteriorly 2-3ds of a line; posteriorly 2-5ths of a line.

Habitation.—Found frequently in considerable numbers in the intestine *Platessa plana*.

[May, 1851. No. 75. See Bibliography.]

Dr. Leidy remarked that in a recent visit to Dr. Wilson, near Newark, Delaware, while rambling in a neighboring wood, upon turning over a log he discovered a mole cricket (*Grillo-talpa americana*) standing very quietly at the mouth of a hole. Upon taking it up the animal exhibited no signs of movement, though perfectly fresh and lifelike in appearance. He took it home and next morn-

ing examined it and found it still presented no signs of life. Every part of the insect was perfect, not even the antennae being broken. Upon feeling it, it was very hard and resistant, and on making an incision through the thorax it exhaled a fungoid odor. The insect had been invaded with a parasitic fungus, which everywhere filled the animal, occupying the position of all the soft tissues, even into the tarsal joints. It formed a yellowish or cream-colored compact mass, and in the abdomen inclosed in its center the stomachal teeth of the insect.

Examined microscopically, the fungus matter was found to consist of a mycelium of filaments for the most part simple, but occasionally branched, and elliptical or globular sporular bodies, averaging 1-233d inch in diameter.

[**May, 1851. No. 76. See Bibliography.]**

CONTRIBUTIONS TO HELMINTHOLOGY.

Ascaris, Linn.

1. *Ascaris Alienata*.—Rud. Entoz. Syn., p. 661; Dujardin Hist. Nat. des Helminth, p. 158.

Body nearly uniformly cylindrical, white; mouth prominent, with the three lips prominent and very distinct; no membranous or other appendages.

Female.—Body cylindrical to within four lines of the mouth, when it gradually becomes narrowed; posteriorly straight, abruptly narrowed into a very small obtuse tail, 1-5th of a line long from the anus; whole length 4 inches 3 lines; breadth 1 and 1-5th lines.

Male.—Cylindrical, attenuated toward the extremities; posterior extremity incurved without appendages; tail short, curved; length 2 inches; breadth 3-4ths of a line.

Habitation—A male and female found in the intestine of *Mephitis americana*. Received from Prof. S. F. Baird, Carlisle, Pennsylvania.

Remark.—It corresponds in every particular except in size, being twice as large, with the *Ascaris alienata* obtained from *Nasua rufa*, described by Rudolphi.

2. *Ascaris Entomelas*, n. s.—Body cylindroid, attenuated at each extremity, curved, whitish, with the black intestine visible through the translucent integument, without membranous appendages; generative aperture posterior to the middle; tail conical, pointed, 1-18th line long.

Length of female 1 to 1½ lines; breadth 1/8 of a line.

Ovum 1.333d inch long; 1-500th inch broad.

Habitation.—Lungs of *Rana halecina*.

Remarks.—Very distinct from *Ascaris nigro-venosa*, Zeder, which is three times as large and possesses membranous appendages. The largest female, with the oviducts distended with eggs of *Ascaris entomelas*, do not measure over $1\frac{1}{2}$ lines. It is also not to be confounded with *Angiostoma entomelas*, Duj., which as a generic character possesses a corneous capsule within the head.

DISTOMUM, RETZIUS.

3. *Distomum Longum*, n. s.—Body whitish, with the blackish ovaries showing through the anterior two-thirds, subcylindrical, compressed; posteriorly subligulate, or spatulate, obtusely rounded; neck cylindrical. Oral acetabulum obliquely terminal, ureolate, broader than the neck, $3\frac{1}{2}$ ths of a line in diameter. Ventral acetabulum a little smaller and from $1\frac{1}{2}$ to 2 lines behind the former; orbicular, projecting $\frac{1}{2}$ a line in diameter. Generative aperture just anterior to the middle of the neck, or nearer the oral acetabulum.

Length 15 lines to 3 inches; breadth 2-5ths to 3-4ths of a line.

Habitation.—Six individuals found in the mouth of *Esox cstor*, Cleveland, Ohio. Received from Prof. S. F. Baird.

Remarks.—This is a remarkable species of *Distomum* from the very great relative length to the breadth.

4. *Distomum Terrecolle*, Rud. Entoz. Syn., p. 102; Dujardin, Hist. Nat. des Helm.; Diesing, Syst. Helm., p. 358.

Body sub-cylindric, light flesh color, posteriorly rounded. Ventral acetabulum $\frac{3}{4}$ ths of a line behind the oral, $\frac{1}{3}$ d line in diameter. Oral acetabulum, $\frac{1}{4}$ th of a line.

Length 8 lines; breadth posteriorly $\frac{1}{2}$ line, anteriorly $\frac{1}{3}$ d line.

Habitation.—Stomach of *Esox reticulatus*, Lesueur.

Remark.—The generative aperture is placed immediately in advance of the ventral acetabulum. When the animal contracts, the two acetabula are nearly brought into contact.

5. *Distomum Rectum*.—Duj. Hist. Nat. des Helm., p. 405; Diesing, Syst. Helm., p. —.

Body whitish, with yellowish brown from the ova; oblong, sub-linear, slightly narrowed anteriorly; posteriorly truncate, slightly sinuous. Oral acetabulum larger than the ventral. Posterior respiratory sinus very large.

Length $\frac{3}{4}$ to $1\frac{1}{2}$ lines; breadth $\frac{1}{4}$ line.

Hab..—Small intestine of *Rana halecina*.

6. *Distomum Cygnoides*.—Zeder, Nachtrag., p. 175; Dujardin, Hist. Nat. des Helm., p. 396; Diesing, Syst. Helm., p. 342.

Body yellowish white, posterior to ventral acetabulum sublinear, or compressed fusiform, subacute; neck cylindrical, translucent. Ventral acetabulum two to three times larger than the oral, cup-shaped.

Length $1\frac{1}{2}$ to 4 lines; breadth 1-5th to $\frac{1}{2}$ line.

Hab.—Urinary bladder of *Rana pipiens*, *Salamandra maculata*, and *Salamandra (Ambystoma) rubra*.

7. *Distomum Variegatum*.—Rudolphi, Syn. Ent., p. 90; Dujardin, Hist. Nat. des Helm., p. 416; Diesing, Syst. Helm., p. 354; *Monostomum ellipticum*, Rud. Entoz. Syn., p. 84; Bremser, Icon. Helm., pl. 8, fig. 12-14; Diesing, Syst. Helm., p. 322.

Body soft, oblong oval, slightly antero-posteriorly compressed; integument translucent, with the black oviduct, white ovary, and brownish or yellowish intestine visible; convex upon the under surface; posteriorly dilated, obtuse. Mouth small, round, with a thick crenated lip, subterminal. Male generative aperture immediately behind the mouth. Ventral acetabulum very small, round, $1\frac{1}{2}$ lines to the mouth.

Length 1 to 4 lines; breadth of largest anteriorly 1 line, posteriorly $1\frac{1}{2}$ lines; thickness 3-4ths of a line.

Hab.—Found frequently in numbers from 1 to 6 in the lungs of *Rana pipiens*.

Remarks.—I was on the point of considering this entozoon as a *Monostomum*, when I was led to examine it more carefully by the observation of Dujardin* that it had been described by authors under the name of *M. ellipticum*, because the ventral acetabulum is very small and difficult to perceive. The latter I found without difficulty in the position stated in the description.

ECHINORHYNCHUS, MÜLLER.

8. *Echinorhynchus Emydis*, n. s.—Body white, cylindrical, slightly narrowed posteriorly, recurved, broadly annulated, smooth, posterior extremity dilated into a small globular portion terminating abruptly or in a short conical, obtuse point. Proboscis subglobular or oval, with a slight transverse row of six strong hooklets and a row in a rudimentary condition; neck very short.

Length 2 to 8 lines; breadth 1-4th to 1-3d of a line.

Hab.—Seventeen individuals were obtained from the commencement of the small intestine of *Emys geographicus*. Received from Prof. S. F. Baird.

* Hist. Nat. des Helm., p. 416.

Remark.—This is, so far as I can ascertain, the first *Echinorhynchus* which has been detected in the Emyidae.

9. *Echinorhynchus Lateralis*, n. s.—Body cylindroid or subfusiform; posteriorly narrowed, with an obtusely rounded extremity. Proboscis cylindrical, $\frac{1}{3}$ of a line long, lateral or subterminal or transversely projected, furnished with 12 transverse rows of strong hooklets, 6 in each row; alternating; neck short. Male without copulatory appendage.

Body from 2 lines to 1 inch in length; breadth anteriorly from $\frac{1}{4}$ -th to $\frac{3}{5}$ -ths of a line; breadth posteriorly from $\frac{1}{5}$ -th to $\frac{2}{5}$ -ths of a line.

Hab.—Seventy-six individuals were found within the intestine, and according to Prof. Baird, from whom they were received, also attached to the integument upon the interior of the body of *Salmo fontinalis*.

Remark.—Closely allied to *E. angustatus*, Rud.

10. *Echinorhynchus proteus*.—Westrumb, De Helm. Acanth., p. 37; Duj. Hist. Nat. des Helminthes, p. 529.

Body orange color, fusiform; anteriorly slightly spherically dilated; posteriorly obtusely rounded. Proboscis cylindrical, with twelve to twenty transverse rows of hooklets, transversely projected, yellow. Neck long, posterior three-fourths filiform, anterior fourth dilated into a spherical vesicle.

Length of body 3 to 6 lines; neck 2 to 3 lines long, $\frac{1}{6}$ -th line broad posteriorly.

Hab.—Found very frequently in the large intestine, often in great numbers, of *Labrax lineatus*.

THELASTOMA, LEIDY.

11. *Thelastoma Brevicaudatum*, n. s.—Body white, cylindrical; anterior to commencement of ventriculus rapidly narrowed, conoidal; posteriorly abruptly rounded, with a very short spiculate tail. Generative aperture just posterior to middle. Anus just anterior to posterior rounded termination. Ventriculus broadly dilated at commencement, and moderately so at termination.

Length of body $\frac{1}{4}$ to 2 lines; anterior to ventriculus $\frac{1}{50}$ th inch; from anus to end of tail $\frac{1}{200}$ th inch; tail $\frac{1}{285}$ th inch long; breadth of body just above anus $\frac{1}{133}$ d inch; at middle $\frac{1}{80}$ th inch; at commencement of ventriculus $\frac{1}{75}$ th inch; cylindrical portion of cesophagus $\frac{1}{66}$ th inch long by $\frac{1}{666}$ th inch broad; pyriform portion $\frac{1}{250}$ th inch long by $\frac{1}{285}$ th inch broad. Ovum semi-oval, $\frac{1}{285}$ th inch long by $\frac{1}{100}$ th inch broad.

Hab.—Found in numbers from one to four in the intestine of larvae of a large lamellicorn insect, found by my friend Mr. S. Powell in earth mould near Philadelphia.

GREGARINA, DUFOUR.

12. *Gregarina*.—Body white, cylindro-fusiform. Superior division presenting four sides of a hexahedron, subacute. Nuclear body of inferior division transparent, globular or elliptical, containing several coarse granules.

Length from 1-66th to $1\frac{1}{4}$ lines; head 1-400th inch to 1-133d inch long by 1-285th inch to 1-111th inch broad. Anterior portion of inferior division 1-200th inch to 1-86th inch broad; posterior portion 1-666th inch to 1-250th inch broad. Longitudinal lines of inferior division more distinct than those of the upper division, 1-800th inch apart.

Hab.—Found in the same insect as the preceding.

Remark.—Since the discovery* of the beautiful parallel, longitudinal line of the inferior division of the body of *Gregarina* after a careful examination I have come to the conclusion that they also exist upon the superior division.

13. *Astacobdella Philadelphica*, n. s.—Body whitish, translucent, sides nearly parallel, a little broader posteriorly, 16 alternately broad and narrow segments exclusive of head and posterior end. Head campanulate, terminated by a circular or elliptical crenated lip fringed with very minute stiff hairs, 1-2000th inch long. Acetabulum circular, 1-6th to $\frac{1}{4}$ th line in diameter. Mouth elliptical. Dental plates brown, nearly equal, forming an isosceles triangle, with the base longest and attached. Apex of superior plate ending in a sharp conical point, with several very minute denticulations on each side. Apex of inferior plate bifurcated into two points, with two minute denticulations on each side. Stomach capacious, nearly filling the anterior, 8 alternately broad and narrow segments posterior to the head. Anus dorsal, 1-5th of a line from the acetabulum. Generative aperture ventral, anterior to the anal aperture.

Length 1 to 4 lines; breadth 1-6th to $\frac{1}{2}$ line. Head 1-6th to $\frac{1}{2}$ line long. Ovum attached by a pedicle, with an operculum pointed at summit. From base of attachment to point of opercle, 1-5th line. Length of body of ovum 1-6th line; breadth 1-8th line.

Hab.—Found frequently in numbers from one to several dozen

* Proc. Acad. Nat. Sci., vol. 4, p. 232, 1849.

upon any part of the exterior of the body of *Astacus Bartonii*, Fab., but more especially upon the inferior surface and branchiae.

MALACOBDELLA, BLAINVILLE.

14. *Malacobdella Grossa*, Blainville.—*Hirudo grossa* Müller, Zoöl. Dan. *Malacobdella grossa*, Blainville, Dic. Sc. Nat., xlvi, 270; Moquin-Tandon, Monag. Hirud.; Diesing Syst. Helm.; *Phylline grossa*, Johnston, Lond. Mag. Nat. Hist., iii, 6-10.

Body yellowish white, compressed pyriform, oblong or elliptical. Integument translucent. Acetabulum yellowish, circular, $\frac{3}{4}$ ths to $2\frac{1}{2}$ or 3 lines in diameter. Protractile proboscis cylindrical, from $\frac{1}{2}$ to 3 lines long. Intestine tortuous. Ovaries upon each side iron gray.

Length from 2 lines to 1 inch, occasionally $1\frac{1}{2}$ inches; breadth from $\frac{1}{2}$ a line to 5 or even 7 lines.

Hab.—Found frequently, usually singly, adhering to the mantle of *Venus mercenaria*, Lin. and *Venus praepara*, Say.

[JUNE, 1851. NO. 77. SEE BIBLIOGRAPHY.]

Dr. Leidy remarked that it had occurred to him whilst examining the mole cricket, referred to at the meeting of May 20, that if the fragments of the insect were placed under favorable conditions, the fungoid matter in the interior of the insect might develop itself into an external form of fungus. He accordingly placed them in a small glass case, with some moist sphagnum, and allowed them to remain until the present time. Dr. L. exhibited the glass case with the fragments, each having sprouted out of it one, two, or three elongated, conical stipes of a cream color, from three lines to 1 inch long, and from $\frac{1}{2}$ to $1\frac{1}{2}$ lines in diameter. Dr. Leidy, continued, in examining insects for entophyta and entozoa, he had found the hemiptera remarkably free from them, which he considers an important fact. Those insects which eat large quantities of vegetable solid food, especially such as eat decaying substances, are very much infected with parasites. The spontaneous generation of entophyta and entozoa finds but few advocates at the present day. Late researches leads us to suspect that many, if not all, entozoa pass part of their life out of the animals in which they are known as parasites, under forms different from those when within the animals.

The entrance of the parasites into other animals is effected probably in two ways: with the food of the latter, or by boring from the exterior. The former method is probably the most frequent in

aerial animals; and both methods are frequent in aquatic animals, because in the latter case the water affords a good vehicle for the approach of the parasites to any part of the body of the animals to be infected.

As hemipterous insects suck the juices only of plants or animals, through a delicate proboscis, they are placed under circumstances the most favorable of all animals to avoid taking in with their food, ova, spores, or developed animals and plants of a parasitic character, whilst insects like *Pussalus*, crickets, etc., or *Julus* among myriapoda, from their eating decaying substances, swallowing large morsels of such food, are very apt to take in parasites.

Frequently I have detected adhering to insects and annelida, while living, cryptogamic sporules, which, under favorable circumstances, before or after the death of the animal, undergo development into the perfect plant. House-flies, and especially earth-worms, are very liable to the growth of *Achlya* upon them, and sometimes I have even detected the growth of the latter upon the surface of earth-worms still living.

[June, 1851. No. 79. See Bibliography.]

HELMINTHOLOGICAL CONTRIBUTIONS NO. 2.

ASPIDOGASTER, BAER.

Aspidogaster conchicola, Baer. Act. Acad. Nat. Cur., T. 13, p. 527; Dujardin, Hist. Nat. des Helm., p. 324; Diesing, Syst. Helm., vol. 1, p. 414.

Body oval, posteriorly obtusely rounded; color yellowish white. Neck translucent, cylindric; mouth terminal, large, surrounded by a thick, contractile lip. Lateral margin of ventral disk crenate.

Measurements at rest.—Length $\frac{1}{2}$ to $4\frac{1}{5}$ ths of a line by $\frac{1}{4}$ th to $\frac{1}{3}$ d of a line broad. Neck $\frac{1}{4}$ th length of body by $1\frac{9}{10}$ th line in breadth. Oesophageal bulb longitudinally oval, $1\frac{1}{166}$ th inch long by $1\frac{285}{100}$ th inch broad. Ovum oval, $1\frac{333}{100}$ d to $1\frac{285}{100}$ th inch long by $1\frac{666}{100}$ th to $1\frac{500}{100}$ th inch broad.

Measurements in action.—Length 1 to $1\frac{1}{2}$ lines by $1\frac{5}{10}$ th to $\frac{1}{4}$ th line broad. Neck may elongate to one-half length of body by $1\frac{200}{100}$ th in breadth. Lip may expand into a circular disk or be elongated into a triangular rostrum.

Hab..—Found in the pericardial cavity of *Unio purpureus*, *U. nasutus*, *U. radiatus*, *U. cariosus*, and *Anadonta marginata*.

PLANARIA, MÜLLER.

2. *Planaria Maculta*. Leidy, Proc. Acad. Nat. Sci., vol. 3, p. 251; Diesing, Syst. Helm., vol. 1, p. 205.

Length from $2\frac{1}{2}$ to 6 lines; breadth $\frac{1}{2}$ to 1 line.

Hab.—Everywhere in ditches near Philadelphia. (Found in great abundance between the outer decaying petioles and inner living ones of the leaves of the *Irum virginicum*, growing in profusion in ditches below the city.)

3. *Planaria Truncata*, n. s.—Body sublinear, posteriorly obtusely rounded, anteriorly truncated, with the angles slightly prominent laterally; blackish white, translucent at margin, with a blackish streak down the back. Eyes two, reniform, 1-400th inch long by 1-500th inch broad, 1-200th inch apart. Oesophagus simple, cylindrical, $\frac{1}{2}$ line long.

Length 3 to 5 lines, breadth $\frac{1}{2}$ to $\frac{3}{4}$ th of a line.

Hab.—Found in a running rivulet in the vicinity of Newark, Delaware.

4. *Planaria (Typhlolepta? Oersted) Fuliginosus*, n. s.—Body oval, dilated; inferiorly flat, superiorly moderately convex, fuliginous. Eyes none: in their ordinary position a slightly greater accumulation of black pigment upon the upper surface. Mouth inferior, a little posterior to the center. Oesophagus simple, cylindrical, white, 1 line long by $\frac{1}{2}$ line broad.

Length 5 lines, breadth 4 lines.

Hab.—Rancocas Creek, near Pemberton, N. J.

ANGUILLULA, OKEN.

5. *Anguillula Longa*, n. s.—Body cylindrical, translucent, colorless. Mouth round, buccal capsule inverted campanulate oesophagus and intestine cylindrical, equal in diameter, the former 1-25th inch long.

Female, 2 to 3 lines long; anteriorly 1-333d inch broad; middle 1-285th inch. Tail narrow, acute, 1-111th to 1-75th inch long from anns.

Male $1\frac{1}{2}$ to 2 lines long; posteriorly dilated, obtusely rounded, curved, with three slight tubercular thickenings of the integument ventrally; 1-285th inch broad; at middle 1-370th inch broad. Penis a curved spiculum, 1-280th inch long.

Hab.—Found in very great abundance, wriggling above the surface of soft mud, in stagnant ditches in the neighborhood of Philadelphia.

6. *Anguillula Longicauda*, n. s.—Body cylindrical, colorless, hyaline; anteriorly obtusely rounded; posteriorly attenuated, with a long, delicate, flexible, subulate tail. Mouth without cirri; œsophagus cylindrical, often with the appearance of a globular bulb at its lower end; intestine cylindrical; anus indistinct. Generative apparatus?

Length 1-40th inch; breadth 1-100th inch; length of tail 1-200th inch. Smallest: Length 1-160th inch; breadth 1-200th inch; length of tail 1-800th inch. In an individual 1-100th inch long, the œsophagus measured 1-570th inch long.

Hab.—Found with *Lyngbya muralis* and other confervæ about gutters and water spouts in the city of Philadelphia. This species is very active in its movements and appears to have the power of fixing itself by the end of the tail to surrounding objects.

7. *Anguillula Fossularis*.—Body cylindrical, anteriorly narrowed, truncated. Mouth round, surrounded by a prominent circular lip; buccal apparatus none; pharynx short; œsophagus long, clavate, or fusiform, slightly tortuous; intestine cylindrical, brown in color; rectum distinct, cylindrical, colorless. Tail acute. Ovary double. Generative aperture anterior to the middle.

Length 2 to $2\frac{1}{2}$ lines; breadth 1-250th inch. Tail 1-80th inch long from anus. œsophagus 1-28th inch long; 1-333d inch broad at commencement; 1-400th inch at termination. Intestine 1-475th inch broad. Rectum 1-75th inch long.

Hab.—Stagnant ponds and rain puddles in the suburbs of Philadelphia.

ACESTUS, LEIDY.

Body vermiform. Podal spines in 4 rows; anteriorly 3 to 5 in each fasciculus, posteriorly in pairs; long sigmoid, bifurcated at extremity. Upper lip conoidal, inarticulate. Annuli under 100. Blood red. Eyes, girdle and muscular stomach none.

8. *Acestus Spiralis*, n. s.—Body cylindrical, posteriorly attenuated, obtusely terminated; color reddish; integument thick. Annuli 80; anterior five with 5 podal spines in each fasciculus, afterwards 3 in each, and posteriorly in pairs; furnished with a shoulder, and a bifurcate unguiform extremity. œsophagus passing the sixth annulus. Intestine simple, cylindrical, capacious. Blood vessels large, tortuous, without distinct coeca, filled with red blood.

Length 1 inch; breadth anteriorly 1-12th line; at middle 1-10th line; posteriorly 1-16th line. Lip 1-280th inch long from mouth. Podal spines 1-400th inch long.

Hab.—In the soft mud at the bottom of stagnant ditches and ponds in the neighborhood of Philadelphia.

Remark.—When drawn out of its concealment in the mud, it rolls the posterior 3-4ths of the body into a spiral.

9. *Aectus Hyalinus*, n. s.—Body cylindrical, posteriorly obtuse, hyaline. Annuli 24 to 34. Podal spines anteriorly 3 to 4 in each fasciculus, posteriorly in pairs, swollen slightly one-third their length from the extremity, which is unguiform and bifurcated. Blood faintly red.

Length $1\frac{1}{2}$ to 3 lines; breadth anteriorly $1\cdot333$ d inch; middle $1\cdot280$ th inch; posteriorly $1\cdot400$ th inch. Lip $1\cdot500$ th inch long. Podal spines $1\cdot550$ th inch long.

Hab.—Found with the preceding, its anterior half buried in the mud, and the tail rapidly vibrating like *Scenurus* or *Strephuris*.

DERO, OKEN.

Body vermiform. Podal spines in two rows. Lateral setæ. Caudal appendages. Blood reddish. Proboscis and eyes none.

10. *Dero Limosa*, n. s.—Body cylindroid, faintly reddish, translucent; 9, 16, 26, to 34 setigerous annulations when the body is in front 1 to 4 divisions. Five anterior annuli without setæ. Two rows of podal spines; 5 to 6 in each fasciculus anteriorly; 3 to 4 posteriorly; long sigmoid, bifurcate at extremity. Setæ single, in one row upon each side. Caudal annulation, expanded, truncated, furnished upon each side of the anal aperture with four unequal, compressed, oval curved, contractile appendages. Upper lip triangular. Oesophagus passing to sixth annulation.

Length 2 to 6 lines; breadth anteriorly $1\cdot10$ th line; middle $1\cdot8$ th line; caudal annulation expanded $1\cdot5$ th line. Lip $1\cdot250$ th inch long. Setæ $1\cdot666$ th inch to $1\cdot133$ d inch long.

Hab.—Living in tubes of mud or decayed vegetable particles, upon the bottom of stagnant ponds and ditches, in the neighborhood of Philadelphia.

It is usually observed with the posterior half or two-thirds of its body projecting nearly vertically from its tube, with the caudal, contractile appendages expanded. Upon any disturbance it rapidly retreats within its tube. A sessile species of vorticella is frequently found attached to the posterior part of the body.

At first sight there appears to be only three appendages each side of the anus, but closer examination proves the existence of a fourth, small and not so distinct.

[June, 1851.]

Dr. Leidy stated that the *Cicada septendecim* was subject to a fungous disease. The posterior part of the abdomen he observed in several instances to be filled with a mass of oval spore-like bodies, embossed upon their surface, but becoming smooth from endosmosis when placed in water.

He also stated that he had just received the dead larva of a lamellicorn insect, which was filled with the same fungus which sometimes attacks the mole cricket.

[August, 1851. No. 82. See Bibliography.]

HELMINTHOLOGICAL CONTRIBUTIONS NO. 3.

GEN. NOV. SYNPLECTA.*

Body nematoid, cylindroid, distinctly and coarsely annulated. Head composed of two trilobed portions, between which is the mouth. Oesophagus long, simple. Intestine narrow, simple. Male, attenuated at the extremities; posteriorly rolled into a spiral, and furnished ventrally with numerous tegumentary tubercles. Penis short, corneous, composed of two lateral portions. Female anteriorly attenuated; posteriorly terminating in a strong, thick muscular acetabulum, with a posterior conoidal depression containing a single strong, recurved hook. Anus and generative apertures close together, just anterior to the muscular acetabulum. Ovum elliptical, elongated at the poles.

The female of this curious genus of nematoid entozoa attaches herself by means of the posterior hook to the mucous membrane of the intestinal canal of the animal it infests, while the male clings to the female by winding the posterior part of its body spirally around the posterior part of the latter, retaining itself in that position through the aid of the numerous tubercles upon its ventral surface, which closely apply themselves to the part of contact in the female.

1. *Synplecta Pendula*, n. s.

Body faintly reddish-white, cylindroid. Annulations with from 12 to 18 transverse muscular striae. Lobes of the head nearly equal. Oesophagus very long, cylindroid, slightly dilated inferiorly. Intestine narrow, cylindrical.

Male.—Length 4 to 5 lines; breadth 1-6th of a line. Posterior fourth of body forming three turns of a spiral, furnished ventrally

*Synplecta:—συν, together; πλέκω, I twine.

with about 20 longitudinal rows of tegumentary tubercles, or small quadrilateral plates 1-1600th inch long by 1-2666th inch broad, extending as far back as the anus. Tail curved, conoidal, 1-60th inch long from the anus, furnished ventrally with 7 or 8 pairs of minute conical tubercles. Oesophagus 1-5th line long, 1-333d inch broad; intestine 1-400th inch broad. Penis 1-200th inch long, conoidal, obtuse, bent at free extremity, composed of two lateral halves.

Female.—Six to 11 lines long, 1-5th to 1-4th line broad. Posterior extremity bent, dilated, terminating in a thick, oval, strongly muscular receptacle or acetabulum, truncated posteriorly and excavated into a deep conical cavity, containing a strong hook, with the point directed forward, 1-200th inch long, with a base 1-400th inch broad. Oesophagus, in an individual 8½ lines long, 1 line long by 1-666th inch broad at commencement, 1-333d inch at termination. Intestine 1-450th inch broad. Ovum 1-570th inch long, 1-333d inch broad.

Habitation.—Stomach and commencement of small intestine of *Emys guttata*.

Remarks.—The female hangs suspended by its posterior hook from the mucous membrane of the stomach of the *Emys*, in which it is parasitic, while the male clings closely to the female by means of its spiral folds, retaining its position readily from the roughness of surface produced by its numerous ventral tubercles, and also those upon the tail. I found this entozoon three times, in 15 individuals of *Emys guttata*. In one instance it was a large female; in the second two, average size females, and one male; in the third instance the stomach was distended with the worms, of which about one in five or six was male, and usually clung to the largest of the females.

CUCULANUS, MÜLLER.

2. *Cuculanus Trispinosus*, n. s.

Body reddish, narrow, cylindrical, finely striated, attenuated at the extremities. Mouth large, sustained by a red or brown corneous capsule, presenting 8 radiating ribs or lines upon each side of a middle line. Oesophagus of two portions; the first elongated pyriform; the second cylindroid, a little dilated at its lower end. Intestine simple, cylindrical, a little narrower than the oesophagus.

Male.—Three lines long, 1-200th to 1-160th inch broad at middle. Posterior extremity curved, acute, furnished on each side ventrally, with an expansion of the integument, of nearly uniform breadth, 1-800th inch, to its termination, commencing 1-50th inch above the end of the tail, and perforated by six nearly equidistant respiratory

canals. Tail 1-300th inch long from anus. Anal and generative apertures indicated by a prominent lip, and separated by a small conical papilla. Penis consisting of two cornaceous, curved, spiculae; 1-56th inch long, the other 1-200th inch long.

Female.—Viviparous, 6 lines long, 1-100th to 1-90th inch broad. Tail straight, long conoidal, 1-111th inch long from anus, obtuse, terminated by three minute points 1-4000th inch long. Generative aperture surrounded by a very prominent lip, a little posterior to the middle. First portion of œsophagus 1-66th inch long: 1-200th inch at broadest part; second portion 1-56th inch long.

Habitation.—Small intestine of *Emys guttata*.

TENIA, LINN.

3. *Tenia Pulchella*, n. s.

White, without any admixture of any other color, variable, usually broadest anteriorly. Head quadrilateral, sub-clavate, obtusely rounded, broader than the neck. Acetabula circular, cup-shaped, lateral and opposite sessile, protractile. Neck very long, cylindroid. Articuli containing several colorless globules; anteriorly subglobular or transversely oval; posterior moniliform, longitudinally oval, or cylindroid and centrally incrassate.

Measurements.—Longest 9 inches. Articuli commencing to be distinctly separate 4 inches from the head. Breadth anteriorly 1-4th line; posteriorly 1-6th line; anterior articuli 1-6th line long; posterior 1-4th line. Acetabula 1-166th inch in diameter.

Smallest 2 inches. Head 1-75th inch broad. Articuli commencing distinctly separate 3-4ths inch from the head. Broadest part of neck 1-90th inch; short distance posterior to the head, 1-125th inch. Anterior articuli 1-100th inch diameter; posterior 1-44th inch long; 1-200th inch broad at extremities, 1-133d inch broad at middle. Acetabula, 1-200th inch diameter.

Habitation.—Small intestine of *Bufo americanus*.

Remarks.—Closely resembles the *Tenia dispar*, Goeze, found in the *Bufo viridis*, etc., but it is relatively longer and narrower, and is never colored.

PLANARIA, MÜLLER.

4. *Planaria Sylvatica*, n. s.

Body elongato-fusiform, thick, becoming narrowed forward, smooth, shining; superiorly convex, grayish with a fuliginous stripe down each side of the dorsal line, and a transverse spot of the same color at or just posterior to the center; inferiorly

compressed, whitish, anteriorly attenuated, proboscidiform; tip recurved, fuliginous, obtuse; posteriorly broadest, terminating acutely. Eyes two, black, globular, lateral, slightly prominent.

Length 2 to 5 lines; breadth at the anterior fourth 1-8th of a line; at posterior fourth, 1-4th of a line.

Habitation.—Beneath stones, flower-pots, and boxes in gardens in Philadelphia, and under fragments of wood, bark, old logs, etc., in forests in the neighborhood of Philadelphia.

Remarks.—This is the first terrestrial *Planaria* which has been detected in North America. I accidentally discovered it first beneath several flower boxes and pots in the small garden attached to my residence in this city, since which I sought for and found it in the hilly woods bordering the Wissahickon creek and Schuylkill river. In its movements it resembles a slug (*Lima.v*), and like this leaves behind it a mucous trail. When in motion the anterior portion of the body is much elongated and very narrow, and the portion anterior to the eyes is recurved. Frequently it raises the anterior third of the body from the ground, moving it from side to side as if in search of something. The recurved portion inferiorly is flat, with the edges often inflected.

When at rest the body is contracted into an oblong form, and the head lies doubled upon the back. The longest will contract to 2½ lines in length by 1½ a line in breadth, and 1-3d line thick posteriorly, and 1-4th line wide anteriorly.

The coloring matter upon the back is arranged in faint transverse annuli, accumulating upon each side of the middle into a longitudinal line, and a transverse spot about the center.

The eyes are globular, apparently composed of a vitreous humor, two-thirds enveloped with a black pigment. They are situated laterally, 1-100th to 1-48th of an inch posterior to the extremity of the head, and measure about 1-500th inch in diameter.

The mouth is inferior and a little posterior to the center. Oesophagus keg-shaped, about 1-50th inch long. From the acute tail end is secreted a delicate mucous thread.

The *Planaria* appears not to like the water, for although it will live for some hours beneath the surface when prevented from rising, yet it always seeks to leave it and remains out when it has escaped.

In the same forest localities with the *Planaria* is found an insect larva, possessing similar habits, which upon careless inspection might be mistaken for it. The movements of the larva are more rapid and vermicular.

PLANARIA, MÜLLER.

SUB-GENUS NOV. BDELLOURA.*

Characters same as *Planaria*, without tentaculae, and the posterior extremity of the body separated by a constriction serving as a disk of attachment.

5. *Bdelloura Parasitica*, n. s.

Body milk white, with a faintly yellowish intestine showing through the translucent integument, smooth, thin, lanceolate, or spatulate; anteriorly narrowed, obtuse; lateral margins, thin, undulating; constricted portion posteriorly truncated, nearly as broad as the middle of the body. Eyes two, reniform. (Esophagus, simple, cylindrical, campanulate when protruded.

Length from 3 to 10 lines; breadth 2-5ths to $2\frac{3}{4}$ lines. The longest may contract to 6 lines by $3\frac{1}{2}$ lines.

Habitation.—Parasitic upon the King Crab, *Polyphemus occidentalis*, Lam. Found often in great numbers, adhering with considerable tenacity by means of the posterior constricted extremity of the body to the under surface of the branchial covers, the branchial laminae, and to the extremities, especially in the vicinity of the joints.

Remarks.—When the King crab is removed from the water its planaroid parasite retires to the deepest recesses between the limbs and other external organs to avoid evaporation. The parasite moves with a gliding motion, like the species of *Planaria*, and also by fixing the posterior extremity and extending the anterior part of the body to its greatest length, and then abruptly detaching and drawing forward the former, like the leeches. At other times it fixes itself posteriorly, and waves the anterior portion of the body to and fro through the water.

Attached to the branchial laminae of the King crab are frequently observed ochreous or brownish, oval, compressed cysts, from $\frac{1}{4}$ to 2 lines long and 1-6th to 1 line broad, attached by a short pedicle at one extremity, and unusually closely applied to the surfaces between the branchial laminae, which are receptacles or ova? of the *Bdelloura parasitica*. Occasionally the margin of the cysts is improved with a fringe of short irregular, blackish filaments. Sometimes these cysts exist in such numbers as to have the appearance of flaxseed sprinkled between the branchial laminae.

6. *Bdelloura Rustica*, n. s.

Body brownish or blackish, translucent, lanceolate; anteriorly narrowed, obtuse, lateral margins thin, undulating; constricted por-

* *Bdelloura*, a leech; tail; because the animal adheres by the tail like a leech.

tion truncated posteriorly, with parallel margins. Eyes two, reniform. Oesophagus simple, cylindrical.

Length 2 to 3 lines; breadth 2-5ths to 4-5ths of a line.

Habitation.—Egg Harbor bay, New Jersey, upon *Ulva latissima*, Linn.

Remarks.—Movements same as in the preceding species. When free in water it moves with great rapidity, and rises to the surface in the manner of the leech or the larva of the gnat.

GEN. NOV. MYZOBDELLA.*

Body elongated, compressed fusiform, smooth. Head continuous with the body, subindibuliform, obliquely ventrally terminal. Mouth central, unarmed. Acetabulum ventrally obliquely terminal, concave, not cornaceous.

7. *Myzobdella Lugubris*, n. s.

Body cylindro-fusiform, in transverse section, elliptical, black olivaceous green, anteriorly narrowed, cylindroid; posteriorly incrassate. From 15 to 18 annulations. Integument translucent, permitting the sacculated intestine of a black green hue to be visible. Acetabulum circular, concave, a little larger than the oral disk.

When elongated 10 lines, by $\frac{1}{2}$ line in breadth posteriorly, 1-5th of a line anteriorly. Will contract to 4 lines by 4-5ths line in breadth.

Habitation.—Parasitic upon the common edible crab, *Lupa dicantha*, M. Edw.; usually found attached about the base of the limbs.

MECKELIA, LEUCKART.

8. *Meckelia Lacva*, n. s.

Body very soft, milk white, in transverse section lenticular, convex above and below; when extended, very much compressed, more especially posteriorly, incrassate rounded just posterior to the head; lateral margins thin, undulating; posterior extremity thin, subacute. Head compressed, conical or hastate, anteriorly obtuse, breadth at base 1 line; lateral cleft $1\frac{1}{2}$ lines long. Generative aperture longitudinally oval.

Greatest length 6 inches; ordinarily 5 inches, by 3 lines in breadth, and 1 line in thickness; may contract to 1 inch in length, by 2 lines in breadth, and $1\frac{1}{2}$ lines in thickness.

Habitation.—In mud and sand under stones, dead shells, etc., in positions uncovered at low tide, upon the coast of Great Egg Harbor, New Jersey.

* Myzobdella:—μύζη, I suck; βόδηλλα, a leech.

Remarks.—The more it is extended the broader and thinner it becomes, especially posteriorly. When free in water, it swims like the eels, and in such cases, the broad surfaces of the body are more or less vertical.

9. *Meckelia Rosca*, n. s.

Body bright flesh-colored with fainter lateral margins, and a central darker line inferiorly; in transverse section oblong, convex superiorly, flattened inferiorly; when elongated, becomes cylindroid; posteriorly, obtuse. Head compressed, conical, or hastate, whitish. Generative aperture distinct, round.

Length 2 to 6 inches; ordinarily about 5 inches.

Habitation.—With the preceding species.

Remarks.—As it elongates it approaches more the cylindrical form, becoming thicker and narrower.

[September. 1851. No. 84. See Bibliography.]

OBSERVATIONS ON THE NATURAL HISTORY OF THE FAMILY OF GORDIACEÆ, SIEBOLD.

Our most common species has been confounded with the *Gordius aquaticus*, L., of Europe, but a striking character at once proves it to be distinct. The caudal extremity of the female is trifurcated, while that of the European species is blunt.* The length is from 4 to 12 inches. Of this species there are several varieties from different localities, which may upon further comparison prove to be distinct species.

To this species the name *Gordius varius* was proposed.

A second species of *Gordius* was obtained by Professor Baird from a spring in Essex county, New York. It is very much more delicate than the former, and from 5 to 7 inches long. The female caudal extremity is blunt. The male caudal extremity is bifurcate and fringed with peculiar epidermoid appendages.

For this second species the name *Gordius lineatus* was proposed. Dr. L. also found several remarkable species of *Mermis*, Dujardin.

Eleven specimens of one species were procured by Dr. Budd from a ditch in New Jersey. These are yellowish white in color, and from 6 to 18 inches in length. To the species the name *Mermis elongata* was given.

A second species was found in a ditch near Philadelphia. It is pure white in color, 8 inches long, and has a peculiar tubercular

* Siebold: Archiv. für Naturg., 1838, p. 303.

thickening of the integument upon the caudal extremity. For this species the name *Mermis crassicaudata* was proposed.

Dr. L. further remarked that he had lately had an opportunity of repeating his former investigations* upon the embryology of *Gordius varius*.

The embryology of *Gordius aquaticus*, L., had been studied and published by Gruby † before he had published his notes, but he did not know it at the time, which he considered important, as the observations conducted in two parts of the world, though differing in several points, were generally confirmatory of one another.

The perfect embryo of *Gordius varius* differs so much from the parent that it is impossible to recognize the latter in the former. This has two circles of protractile tentaculæ, each of six, and a protractile proboscis, not uncinate, however, as in the embryo of *Gordius aquaticus*,‡ no trace of which exists in the parent. The body of the embryo consists of two portions, and is distinctly annulated, while the parent is simply hairlike in form, and has no trace of an annulated integument. Gruby remarks he never saw the *Gordius*, excepting the embryo, shorter than $3\frac{3}{4}$ inches,§ so that between the annulose, tentaculated embryo, in the *Gordius varius* the 1-466th of an inch in length, and the parent of at least $3\frac{3}{4}$ inches, nothing whatever is known of the history of the animal. Gordii have been stated upon numerous and the most reliable authorities to have been seen in the body of insects, so that from the embryo to the parent there may probably be a series of forms in alternating generation, entozoic and ectozoic, as numerous and unlike as has been observed in the development of certain species of *Distoma*.

The *Gordius varius* is prolific in a very remarkable degree. A female 9 inches in length, placed in a tumbler of water September 25, up to the present time has extruded a string of ova 49 inches in length, and still actively continues the process.

[September, 1851. No. 86. See Bibliography.]

Dr. Leidy further stated as follows:

The female *Gordius* which he had mentioned at the last evening as having extruded from September 25 up to that time a cord of ova 49 inches in length had continued the process until Sunday evening, October 7, up to which time it had expelled, in fragments

* No. 57. See Bibliography.

† Archiv. für Naturg., 1849, p. 358.

‡ Archiv. für Naturg., pl. 7, fig. 10.

§ Ib., p. 374.

from a few lines to one foot in length, in all a cord 91 inches long, in which he estimated there were over 6,000,000 ova. Dr. L. exhibited the cord of ova preserved in alcohol, which was long and white and resembled a piece of cotton thread.

[October, 1851. No. 87. See Bibliography.]

Dr. Leidy remarked the members probably recollect that a few evenings since he had mentioned that it had been asserted by numerous and good authorities that *Gordii* had been observed within the body of insects. He now exhibited a specimen of a *Gordius* and a grasshopper preserved in a bottle of alcohol, which had been sent to him by his friend, Dr. Budd, of Pemberton, N. J. The *Gordius* Dr. Budd stated was seen to come out of the body of a grasshopper, and in half an hour afterwards died. It is a different species from those described a short time since. It is a female, about six inches long by half a line in length, rigid, strongly marked by transverse wrinkles and annuli, with the caudal extremity somewhat compressed and obtuse. To the species he gave the name *Gordius robustus*.

He also exhibited a species of *Mermis* from Brazil, belonging to the collection of the Academy. It is fourteen and a half inches long and of yellowish brown color. To it he gave the name *Mermis ferruginea*.

[October, 1851. No. 91. See Bibliography.]

LUMBRICULUS, GRUBY.

- Acestus*, Leidy. Proc. A. N. S., V, 226.

Characteribus reformatis. Body filiform, cylindroid, hyaline. Podal spines in 4 rows, in fasciculi of 2 to 5, furcate. Upper lip simple, conoidal. Girdle none. Eyes none. Blood bright red.

1. *Lumbriculus Spiralis*, Leidy.

Acestus spiralis, Leidy : Pr. A. N. S., v. 226. Description from the young ; found in the spring of the year.

Adult.—Body very long and delicate, filiform, cylindrical ; posteriorly obtusely rounded. Upper lip compressed, conoidal. Annuli over 200. Podal spines in 4 rows, 3 to 5 anteriorly, 2 to 3 posteriorly in each fasciculus, long sigmoid, furcate. Intervals of the viscera distended with globular corpuscles, which, shining through the translucent integument, give the annuli a deep greenish or bluish white opalescent appearance.

Length from 1 to 3 inches ; breadth from 1-8th to 1-5th line. One of three inches in length had 276 annuli.

Habitation.—In the mud about the roots of *Pontederia cordata*, *Sagittaria sagittifolia*, and *Arum virginicum*, in ditches below Philadelphia. It is also often found coiled up in a remarkably close knot among the outer decaying petioles of the leaves of the plants just mentioned. Months of August and September.

2. *Lumbriculus Hyalinus*, Leidy.

Acestus hyalinus, Leidy : Proc. A. N. S., v. 226. Description from the young in the Spring.

Adult.—Body filiform, red in color, the posterior fifth yellowish, translucent. Upper lip sub-acute. Caudal annulus obtuse. Annuli from 120 to 180. Podal spines in fasciculi of from 3 to 8, furcate.

Whole length 2 inches, with usually 150 annuli ; breadth anteriorly 1-5th line, posteriorly 1-6th line. One of 1 inch is about 1-6th line anteriorly, 1-8th of a line posteriorly.

Habitation.—Found in ditches with the preceding, the anterior two-thirds of the body buried in the mud, with the tail rapidly vibrating like *Saenirus* or *Strephuris*. Months of August and September.

CHÆTODEMUS, GENUS NOVUM.

Body cylindroid. Upper lip very large and broad. Podal spines in 4 rows, fasciculate, aristate. Mouth large, inferior : pharynx capacious, œsophagus cylindrical ; intestine capacious. Eyes none. Blood colorless. Increasing by segmentation.

1. *Chætodemus Panduratus*, Leidy.

Body transparent, colorless. Upper lip panduriform, broader than the body. Podal spines in fasciculi of 4, long sigmoid, aristate, divergent, 1-666th inch long, commencing with the oral segment. Pharynx oval ; œsophagus narrow, cylindrical ; intestine large, narrowing posteriorly.

Whole length of an individual of three segments 1 line; breadth 1-570th inch. Breadth of upper lip 1-500th inch. First segment of the body with 7 annuli; second with 5; the third with 9.

Habitation.—Found in stagnant ponds and ditches.

Remark.—Allied closely to *Acolosoma*.

STYLARIA, LAMARCK.

1. *Stylaria Paludosa*, Lamarck.

Nais proboscidea, Linn. Syst. Nat., 13th ed., vol. i, pt. 6, 3121.

Body cylindroid, colorless, transparent. Without segmentation from 15 to 20 annuli; one of two segments 40 annulations. Podal spines, 7 to 10 in each fasciculus, long sigmoid, hooked and bifid at the free end. Setæ commencing after the fifth annulus from the mouth, usually single, occasionally two, from 1-400th inch to 1-66th inch in length. Caudal annulus truncated, sinuous, fringed with short stiff hairs. Upper lip broad, emarginate, with a cylindroid, flexible, proboscidiform appendage from 1-33d to 1-25th inch long projecting from its notch, fringed with short stiff hairs. Eyes two, transverse reniform, situated one on each side of the mouth. Mouth triangular; pharynx capacious, œsophagus cylindrical, terminating in the intestine at the third setous annulus.

Whole length from 2 to 4 lines; breadth 1-6th line.

Habitation.—In ditches and ponds in the neighborhood of Philadelphia.

2. *Stylaria Fossularis*, Leidy.

Body of two segments, composed of 24 annuli in the first, 22 to the last. Podal spines 5 to 7 in each fasciculus. Setæ commencing after the fifth annulus, usually double, to 1-66th inch long. Upper lip broad, demi-oval, compressed, not emarginate, with a cylindroid, flexible, proboscidiform appendage 1-33d inch long projecting from its summit. Eyes two, transverse, one on each side of the mouth. Pharynx capacious, extending to the 4th annulus; œsophagus cylindroid, tortuous, extending to the 7th annulus.

Whole length 4½ lines; breadth 1-6th line.

Habitation.—Found with the preceding.

ANELCODISCUS, GENUS NOVUM.

Body cylindroid, smooth, posteriorly terminated by a cordiform, retractile acetabular disk. Mouth and anus terminal. Intestine simple, straight.

1. *Anelcodiscus Pellucidus*, Leidy.

Body cylindroid, colorless, transparent; anteriorly rounded, obtuse; posteriorly spreading into a cordiform disk for attachment. Disk retractile; when retracted, the body becoming dilated oval in the middle and the posterior part doubly intussuscepted.

Length 1-100th inch; breadth 1-100th inch.

Habitation.—Parasitic within the intestine of *Stylaria fossularis*.

Remarks.—From the translucency of the last-mentioned worm, its parasite may be seen within the intestine attached to the mucous membrane by means of its posterior cordiform disk. While attached it alternately retracts its body with a jerk, and then lengthens itself; in the former movement the posterior third of the body becoming doubly intussuscepted, so as to have the appearance of a double articulation. When detached the same movement takes place, but in that of retraction the cordiform disk is entirely drawn within the animal's body. More details of this curious parasite I did not obtain, for although I saw three, and removed them from the intestine of the *Stylaria*, yet their movements were so active I could not study them to advantage, and to quiet them I tried a minute portion of the vapour of chloroform, which instantly killed them, but at the same moment they underwent total destruction. Since then I have not been able to examine others.

GREGARINA, DUFOUR.

1. *Gregarina Scarabei relictii*, Leidy.

Gregarina, Leidy. Pr. A. N. S., v, 208. Found in the larva of *Scarabeus relictus*.

Emea, Leidy. Pr. A. N. S., v, 125.

Characteribus reformati. Body linear, compressed. Head continuous with the body, with two lenticular depressions upon each side. Mouth infero-terminal. Oesophagus styliferous. Eyes 4 to 6 anterior. Fresh water *Nemertinea*.

1. *Emea Rubra*, Leidy. Pr. A. N. S., v, 125.

Body contracting irregularly, reddish or yellowish flesh colored. Anteriorly and posteriorly obtusely rounded. Eyes two or three black spots, placed in a line behind one another, upon each side of the head; often irregular. First pair of lateral depressions opposite the interspace of the anterior two pairs of eyes; second pair just postero-lateral to the posterior pair of eyes. Oesophagus very long and tortuous, villous, furnished at its bottom with a single spine or nail-like tooth, and four others upon each side in a rudimentary condition, enclosed in a sac. Intestine becoming obliterated posteriorly.

Ordinary length from 1 to 6 lines; breadth from 1-8th to 1-5th line. Occasionally 10 lines long by 1-3d broad.

Habitation.—In marshes, ditches, and stagnant ponds in the vicinity of Philadelphia.

Variety a.—White, 2 lines long; 1-6th line broad.

Habitation.—On the under side of stones in the Schuylkill river.

Remark.—I have sometimes met with the largest sized females without the appearance of a developed ovum, and at others, those of from 1 to 3 lines in length, with from 3 to 18 large yellow eggs.

2. *Emea Dugesii*, Leidy.

Polia Dugesii, Quatrefages. *Rech. Anatom. et Zoolog.*, ii, 211.

DENDROCOELUM, OERSTED.

Characters same as *Planaria*, with the head furnished with a hemispherical coryloid cavity, capable of eversion into the form of a pediculated discoidal acetabulum.

1. *Dendrocoelum Superbum*, Girard. *Proc. Bost. Soc. Nat. Hist.*, iii, 265. Keller and Tiedemann, *Nordamerik. Monatsb.*, ii, 2.

Body thin, plano-convex, translucent white, with the sides nearly parallel; anteriorly truncated, with the lateral angles slightly projecting; posteriorly obtusely angular. Coryloid cavity of the head prominent, opening at the anterior truncated margin, when everted presenting the form of a circular disk supported upon a broad columnar contraction of the head. Eyes two, nearly globular, composed of a transparent vitreous humor enclosed at the postero-internal half by a black choroid. Oesophagus long, keg-shaped; intestine delicately and minutely ramified, brown or blackish-brown in color.

Length 3 to 8 lines; breadth 2-5ths to 4-5ths of a line. The longest may contract to 3 lines to 4-5ths in breadth.

Habitation and Remarks.—In ditches communicating with the Delaware and Schuylkill rivers, below Philadelphia, creeping upon the submerged stems of *Arum virginicum*, *Pontederia cordata*, *Nelumbium luteum*, and *Zizania aquatica*.

When seized or irritated it everts its acetabulum, by which it attaches itself to surrounding bodies with the tenacity of a leech.

RHYNCHODEMUS, GENUS NOVUM.

Body cylindroid, ob-fusiform. Head continuous with the body, proboscidiform, recurvatile, without tentacular appendages. Eyes two lateral. Interior structure planaroid. Terrestrial.

1. *Rhynchodemus Sylvaticus*, Leidy. *Pr. A. N. S.*, v, 241.

2. *Rhynchodemus?* *Terrestris*, Leidy.

Fasciola terrestris, Müller.

Planaria terrestris, Gmelin, Syst. Nat., 3092 : Duges, An. Sc. Nat., 21, 82, pl. 2, fig. 18 ; Oersted, Entw. d. Plattw.; Diesing, Syst. Helm., i, 206.

BDELLOURA, LEIDY. PROC. A. N. S., V, 242.

Body dilated, plano-convex ; posteriorly dilated, constricted, truncated. Head continuous with the body ; tentacular appendages none. Mouth inferior, sub-central ; oesophagus protractile, cylindrical. Eyes two. Marine.

1. *Bdelloura Parasitica*, Leidy. Ib.

2. *Bdelloura Rustica*, Leidy. Ib., 243.

3. *Bdelloura?* *Longiceps*, Leidy.

Planaria longiceps, Duges, An. Sc. Nat., 21, 83, pl. 2, fig. 21 ; Diesing, Syst. Helm., i, 207.

PLANARIA, MÜLLER.

1. *Planaria Maculata*, Leidy : Pr. A. N. S., iii, 251 ; v, 225. *Dugesia maculata*, Girard : Keller and Tiedemann, Nordam. Monatsb., ii, 23.

Body thin, spatulate, with sharp, nearly parallel, lateral margins ; anteriorly thin trapezoidal, the latter angles formed by an acute, angular, erectile tentacular appendage ; posteriorly sub-acute ; superiorly a little convex, irregularly maculated with black, in the young sometimes with brown ; inferiorly translucent whitish. Eyes two, reniform, proximate, situated at the inner side of an oval translucent space.

Length from 2 to 8 lines.

Habitation.—In ditches and ponds in the neighborhood of Philadelphia ; upon the under side of stones in the Delaware and Schuylkill rivers, abundant.

Variety a.—Brownish, indistinctly maculated.

Length 8 lines.

Variety b.—Maculations grayish, indistinct, with the intestine blackish, brownish, or greenish, frequently with a lighter stripe down the back.

Length 6 lines.

Habitation.—Schuylkill river, under stones.

CATESTHIA, # GENUS NOVUM.

Body very soft, cylindroid. Head continuous with the body. Mouth infero-terminal; œsophagus amphoraform. Eyes two, deeply seated in the interior of an oval translucent space of the integument.

1. *Catesthia Stellato-Maculata*, Leidy.

Body long, cylindroidal; anteriorly and posteriorly obtusely rounded; superiorly maculated closely and regularly with very much branching, stellate, black pigment cells, which cease abruptly latterly, and anteriorly form 3 lobes, in the translucent whitish interspaces of which, deeply seated, are the eyes, which are black and globular; inferiorly translucent whitish. Mouth round, very large and dilatable; œsophagus amphoraform, very large.

Length 3 to 8 lines, breadth 1-4th to 1 line; thickness 1-5th to 4-5ths line.

Habitation.—Upon the under side of stones in the Delaware and Schuylkill rivers, below tide-water mark.

Remarks.—Closely allied to *Vertebrata*, Hemp. and Ehrenb., but has not four eyes, and has a differently arranged generative apparatus.

It is exceedingly voracious. I have seen an individual of 8 lines in length swallow whole a *Planaria maculata* 6 lines in length.

[December, 1851. No 98. See Bibliography.]

CONTRIBUTIONS TO HELMINTHOLOGY.

MICROSTOMUM? OERSTED. (EUSTOMUM.)

Body elongated, compressed, cylindroid, vibrillated, increasing by transverse segmentation in pairs. Head continuous with the body, furnished upon each side with a respiratory fovea. Mouth antero-inferior; intestinal canal produced anterior to the mouth in the form of a cæcum; œsophagus amphoraform, muscular, not protractile; anus at first (after segmentation) open, afterwards becoming closed. Ocelli none. Minute rhabdocæla inhabiting fresh water.

This genus is the *Microstomum* of Oersted, if what I have observed to be lateral respiratory foveæ of the head are, according to him and other authors, ocelli destitute of pigment.

In numerous individuals of what I have considered below to be of three distinct species of the genus they were always observed to be in a state of division by pairs, and the primary pair of segments

* *Catesthia*: *Kατεσθίω*, devour.

about their middle had already developed respiratory foveæ and were slightly indented preparatory to division before the first pair were separated.

1. *Microstomum (Eustomum) Philadelphicum*, Leidy.

Body linear, slightly attenuated posteriorly; head conoidal, with the apex surmounted by a small oval papilla; tail obtusely rounded. Respiratory fovea sub-hemispherical, placed at the base of the cone of the head. Mouth oval, protractile; œsophagus keg-shaped, intestine narrowed, cylindroid, dilated at the commencement; colorless, translucent, vibrillated, increasing by transverse segmentation, always observed in the process of forming two segments.

Length 2-5ths line by 1-500th inch broad.

Habitation.—Found in the water of marshes and ditches in the neighborhood of Philadelphia.

2. *Microstomum (Eustomum) Variabile*, Leidy.

Body broad, linear; anteriorly and posteriorly obtusely rounded. Respiratory fovea, longitudinally oval, lateral. Intestine very broad; colorless, increasing by twos.

Length from 1-80th to 1-24th of an inch by 1-800th to 1-400th inch broad.

Habitation.—With the preceding.

3. *Microstomum (Eustomum) Caudatum*, Leidy.

Body long, narrow, linear; anteriorly obtusely rounded, posteriorly ending in a narrow, blunt, elevated tail 1-400th inch long from the position of the anus; increasing by twos, the tail of the anterior segments projecting above and its whole length posterior to the head of the succeeding segment.

Length 3-4ths to 1 $\frac{1}{4}$ lines; breadth 1-300th to 1-250th inch.

Habitation.—With the preceding.

Rhynchodemus Sylvaticus, Leidy. Pr. A. N. S., v, 289. Error of reference.

Planaria sylvatica, Leidy. Ib., 241.

Stylaria Fossularis, Leidy. Ib., 287. A number of individuals in a state of segmentation, from which the species was first described, preserved alone in a glass vessel with some confervæ; upon the occurrence of cold weather passed into the perfect condition as follows:

Body long, cylindroid, hyaline, permitting the ash-colored or yellowish intestine to be seen through the integument, divided into from 50 to 65 annulations, furnished with a distinct girdle posterior to the third annulus from the mouth, which extends the breadth of three annuli. Podal hooks in fasciculi of 10 to 12. Setæ commen-

ing after the girdle, usually one, often two, upon each side of the annuli. Head obtusely rounded and prolonged into a cylindroid, very movable, digitiform, transversely wrinkled proboscis. Caudal annulus terminating in two short lobes.

Length 3-4ths to 1 inch; breadth 1-5th to 1-4th of a line. Length of proboscis 1-20th inch.

Remarks upon the Habits.—When at rest the worm lies with the anterior four-fifths of the body upon the surface of the mud at the bottom of the water, with the tail fifth buried. It is very active in its movements. It also constructs tubes of mud. It is hermaphrodite, and copulates in the same manner as the earth worms.

In a number of individuals I observed bunches of spermatozoa, and in several of the same from three to five nearly completely formed ova placed just posterior to the girdle. The eggs when extruded were attached to the inside of the vessel in which the worms were kept. They consisted of an oblong quadrilateral translucent, whitish, papyraceous web, enclosing a light amber-colored, bottle-like case, with an open neck, and the body containing white globular mass, the true egg.

The perfect worm after living about two months died. Some of the ova several weeks after their extrusion were observed to have the young almost perfected, and these a few days after their escape presented the following characters :

Body cylindroid, divided into 35 annulations, each with a pair of fasciculi of four or five hooks; posterior to the first three also provided on each side with one or two setæ. Tail bilobed. Head as in the parent. No girdle; no indication of division, and no apparent developing annuli at the tail end. Length 2 lines.

[November 1853. No. 128. See Bibliography.]

Dr. Leidy stated that the nodular bodies imbedded in the tails and fins of the fishes presented by Dr. Webber, of Charlestown, N. H., were most probably indurated entozoon sacs. Many ponds and lakes contain a minute worm, resembling in general form a tadpole, belonging to the genus *Cercaria*. The species, after living for some time in the water, attach themselves to fishes and other living animals, and, after losing the tail, form for themselves cysts in the integuments, and subsequently become transformed into a parasitic worm of the genus *Distoma*.

[December, 1855. No. 151. See Bibliography.]

NOTICES OF SOME TAPE WORMS.

BY JOSEPH LEIDY, M. D.

1. *Tænia Solium*, Lin.

Hab.—Occasional in the Anglo-American and in the Negro. I have one specimen with segments 6 lines long by 2 lines wide, obtained by Prof. Agassiz, from an Indian of Lake Superior.

Note.—Among all the tape worms from man which I have seen in this country—and I have taken the trouble to examine specimens in many localities—I have never yet met with the *Dibothrium latum* (*Bothrioccephalus latus*).

2. *Tænia Laticephala*, Leidy. Head large; acetabula opposite, very prominent, hemispherical; mouth slightly prominent, unarmed. Neck short. Anterior segments of the body short, oblong square, posteriorly square. Generative apertures marginal, alternate. Protruding penis; elongated conical. Length of one specimen 9 inches, greatest breadth $\frac{3}{4}$ of a line. Breadth of head $\frac{1}{2}$ a line; of neck $\frac{1}{4}$ a line.

Hab.—The small intestine of *Hystrix dorsata*.

3. *Tænia Serrata*, Goeze. Head not broader than the neck, convex anteriorly; mouth prominent, furnished with a circle of strong hooks. Neck long. Anterior segments transversely oblong or cuneate; posteriorly square. Length of three specimens 9 to 12 inches; greatest breadth $1\frac{1}{2}$ lines. Breadth of head $\frac{1}{3}$ a line.

Hab.—From the small intestine of an Esquimaux dog, which was brought from the Arctic regions of North America by the eminent naval navigator, Dr. E. K. Kane, U. S. N.

4. *Tænia Cucumerina* Bloch.

Hab.—Common in the small intestines of all varieties of our dogs.

5. *Tænia Elliptica*, Batsch.

Hab.—Common to the domestic cat.

6. *Tænia Crassicollis*, Rudolphi.

Hab.—Numerous specimens were obtained from the small intestine of a single cat.

7. *Tænia Pusilla*, Goeze.

Hab.—Not uncommon in the introduced Norway rat.

8. *Tænia Pectinata*, Goeze.

Hab.—Eight fragments from 1 to 4 inches long, with the greatest breadth $1\frac{1}{2}$ lines, and having cuneate segments, short and broad, were obtained from the small intestine of *Lepus sylvaticus*.

9. *Tænia Expansa*, Rudolphi.

Hab.—The anterior two feet of a specimen were obtained from the small intestine of an ox.

10. *Tænia Bacillaris*, Goeze?

Hab.—Several fragments, each almost an inch in length and half a line in breadth, with short and broad cuneate segments, were obtained from the intestines of *Scalops aquaticus*.

11. *Tænia Postifera*, Leidy.

Head small, continuous with the neck; acetabula terminal and oblique, hardly prominent beyond the outline of the neck, hemispherical. Mouth not prominent, unarmed. Neck long. Segments cuneate: those anterior short and broad, those posterior longer.

Hab.—Three specimens from $1\frac{1}{2}$ to 2 inches long, with the greatest breadth 2-5ths of a line, were obtained from the small intestine of *Molothrus pecoris* by Prof. Baird, and one specimen $4\frac{1}{2}$ long, with the greatest breadth $\frac{2}{3}$ ds of a line, was procured from the small intestine of *Dolichonyx oryzivora*.

12. *Tænia Strigis Acadicæ*, Leidy.

Two specimens, each about $1\frac{1}{2}$ inches long and apparently consisting of the whole body, except the head and neck, were obtained by Prof. Baird from the small intestine of *Nyctale acadica*. The body is compressed cylindroid, with the anterior segments narrow, conical and those posteriorly moniliform. Breadth anteriorly $\frac{1}{6}$ th of a line: posteriorly $\frac{1}{3}$ d of a line.

13. *Tænia Variabilis*, Rudolphi?

A fragment 3 inches long and 1 line wide was procured by Prof. Baird from the intestine of *Scolopax minor*. Segments short, broad, and subcampanulate, the infero-lateral borders being everted.

14. *Tænia Dispar*, Goeze.

Several specimens obtained by Prof. Agassiz from the intestine of *Menobranchus maculatus*, without the head, are 3 inches long and $\frac{1}{2}$ a line wide, and have longitudinally oblong segments, with lateral and alternate marginal generative apertures and filiform penes. I further have obtained four specimens from *Rana pipiens* and two about 6 inches in length from *Bufo americanus*.

15. *Tænia Lactea*, Leidy. Head small, continuous with the neck, without rostellum; acetabula anterior, hemispherical, situated at the four angles. Neck moderately long. Segments anteriorly transversely oblong, posteriorly longer than the breadth, square with rounded angles. Generative apertures marginal (indistinct in the specimen).

Hab.—One specimen 16 inches long and $\frac{2}{3}$ ds of a line wide was found in the intestine of *Tropidonotus sipedon*. In alcohol the specimen contracted to one-half the original length and widened to 1 line.

16. *Tænia Gibbosa*, Leidy. Head minute, discoid; acetabula horizontal, contiguous, circular. Mouth not prominent, unarmed. Neck long, broad, and thick. Segmented portion of the body comparatively short; segments transversely oblong; the last one discoidal. Generative aperture not seen.

Hab.—Two specimens, $1\frac{1}{2}$ inches long, with the greatest breadth $1\frac{1}{3}$ lines, were obtained by Dr. Le Conte from the intestine of a species of *Lamna* inhabiting the Pacific coast of North America.

17. *Dibothrium Punctatum*, Rudolphi. Head 1 to $1\frac{1}{2}$ lines long; oblong; bothria marginal, linear. Neck none. Anterior segments cuneate or triangular; posterior ones quadrate; each with an appearance of three subdivisions, with the subsegments having a pair of generative apertures in the course of a longitudinally depressed, dark-colored line passing the length of the body.

Length 1 foot, greatest breadth $1\frac{3}{4}$ lines.

Hab.—Intestine of *Platessa plana*.

18. *Ligula Monogramma*, Creplin.

A specimen imperfectly developed, 6 inches long, with the greatest breadth 6 lines, was obtained from the abdominal cavity of the *Morpha americana*, and two specimens of almost the same length, with the greatest breadth 5 lines, were obtained from the abdominal cavity of *Leuciscus pulchellus*.

[**No. 152. See Bibliography.]**

EXTRACT FROM "CONTRIBUTIONS TOWARDS A KNOWLEDGE OF THE MARINE INVERTEBRATE FAUNA ON THE COASTS OF RHODE ISLAND AND NEW JERSEY."*

DENDROCOELA.

Monocelis Agilis, Leidy. Body elongated elliptical, anteriorly and posteriorly subacute, black or fuliginous. Eye brown. Length one line, breadth one-eighth of a line. Found actively creeping on *Mytilus edulis*. Point Judith.

Planaria Frequens, Leidy. Body spatulate, posteriorly convex, anteriorly narrowed; head auriculate. Eyes two, reniform, distant. Color above black, beneath gray. Length one to two lines, by one-sixth to two-fifths of a line in breadth. A small, quite active, and

* Journal Acad. Nat. Sci., Phila., 1855.

remarkably abundant species, found beneath stones, near high-tide mark. Point Judith.

Nemertes Socialis, Leidy. Body long, linear, flattened, anteriorly subacute, anteriorly obtuse or subacute; usually black above, and brownish ash-colored beneath, occasionally brownish ash-colored with the anterior extremity tipped with black. Head not constricted from the body. Eyes two to four pairs, arranged longitudinally on each side, length up to six inches, by one-third of a line in breadth. Very abundant, often in masses, about the roots of corallines between tides. Point Judith.

Meckelia Ingens, Leidy. Body long, tape-like, narrowed posteriorly, cream-colored. Head obtusely angular, depressed; lateral fissures deep. Generative aperture a longitudinal fissure. Described from a specimen preserved in alcohol, and measuring in its present condition fifteen inches in length, eight lines in breadth, and three and a half lines in thickness. It was obtained by Mr. Chas. C. Ashmead from an oyster bed at Beesley's point, New Jersey, and when alive measured more than a yard in length.

NEMATOIDEA.

Pontonema, Leidy. Body capillary, narrowing toward the extremities. Head continuous with the body, obtuse, pointed, with short cirri. Eyes none, caudal extremity obtuse. Generative aperture near the middle of the body. Esophagus long, cylindrical; intestine cylindrical. Ovaries two. Allied to Amblyura. Marine.

Pontonema Vacillatum, Leidy. Body cylindroid, with minute cirri anteriorly in addition to those around the head. Tail short, obtuse, incurved. Color brownish white. Length to three-fourths of an inch, by one-fifth of a line in thickness. Found abundantly beneath stones, between tides, at Point Judith.

Pontonema Marinum, Leidy. Body cylindroid. Tail long, narrow, blunt. Color white. Length to three lines. Obtained from an oyster bed, in about six feet of water, in one of the sounds near Atlantic City, New Jersey.

ENTOZOA.

Gregarina ——. Body elliptical; head oblate spheroidal. Length .225 mm., breadth .072 mm. From the intestine of *Nereis denticulata*.

Lencophrys Clavata, Leidy. (Journ. Acad. Nat. Sc., ii, 50.) In the visceral cavity of *Lumbriculus tenuis*.

Leucophrys Cochleariformis, Leidy. (Pl. XI, figs. 62, 63.) Body curved cochleariform. Length .135 to .18 mm. From the intestinal canal of *Lumbriculus tenuis*.

I found four individuals of this remarkable species in a dozen of the *Lumbriculus*. While within the intestine it appears quiescent, but when set free it moved about actively, by means of its long vibrating cilia, with the bowl-end forward.

ANNULATA.

Naraganseta, Leidy. Body cylindrical, narrowed posteriorly; no lateral pinnæ; segments numerous; those anteriorly furnished with a few simple cylindrical, lateral tentaculæ; anterior segments with four rows of simple setæ in fascicles; succeeding few segments with two rows of simple setæ, and two rows of cochleariform podal spines; posterior segments with four rows of cochleariform spines. Upper lip distinct, conical, eyes none.

Naraganseta Coralii, Leidy. (Pl. XI, figs. 46-48.) Body black, brownish or yellowish black, ninety segments in an individual, one inch and a quarter in length. Eight comparatively short tentaculæ on each side of the anterior six segments; three to the first segment; first two the shortest, the third the most robust; orange in color, and except the most robust one, tipped with black. Anterior ten segments with four rows of simple setæ in fasciculi of five; the succeeding four segments with two rows of simple setæ, and two rows of cochleariform podal spines; and the following segments with four rows of cochleariform podal spines in fasciculi of four to six. Point Judith.

This curious worm lives in tubes within the dead portions of *Astrangea astraeformis*. It protudes the anterior part of its body with the orange colored antennæ. The latter are contractile, from one to four lines long, and, with the exception of the third or more robust one on each side, are tipped with black, as if to be subservient to the impressions of light. Its setæ are quite simple, as represented in figure 47, and are about the fifth of a line in length. The podal spines consist of a long style ending in a bowl, like that of a spoon, as represented in figure 48.

For the new genus, of which the worm just described is the type, I have adopted the Indian name Narragansett, being that of the bay on the shores of which the animal was first discovered.

Sabella Oculifera, Leidy. (Pl. XI, figs. 55-61.) Body demicylindrical, posteriorly narrowed, one hundred and thirty-eight setiger-

ous segments to an individual one and a half inches in length. Tentaculæ twenty-four in number, arranged in the four-fifths of a circle, decreasing in length towards the extremities of the latter, reflected, supplied with about forty-eight secondary tentaculæ, arranged in pairs; two or three black eye spots on the back of the long tentacule. Two rows of setæ in fascicles of about six, and two rows of podal hooks in transverse series of ten. Setæ in the third to the ninth segment inclusive, in major part spade-shaped with a short subulate point; of the following segments all like the latter. Podal hooks in the first to the tenth segments inclusive, bird-like in form, associated with opposing spade-like podal spines. Podal hooks of the following segments smaller than those anteriorly. Worm living in tough tubes composed of mud, and found in a horizontal position partially concealed beneath masses of *Astrangia astraciformis*. Point Judith.

The plumose tentaculæ with the dark eye specks on their back render this worm a beautiful object. The surface of the tentaculæ is everywhere covered with vibrating cilia. By transmitted light the blood appears of a bright green color.

Clymena Urocolatus, Leidy. Body cylindrical, composed of segments of various lengths, twenty-six in number, including the head and caudal appendage. The anterior eight segments the shortest; the seven preceding the last ten the longest; those in advance of the third, and intervening to this and the sixth and the ninth, without setæ. Head obliquely truncated, concave, with a thin acute margin. Mouth inferior triangular. Caudal appendage large, urceolate, with the margin entire. Color reddish brown. Length five inches; breadth one and a half lines. Raked from the mud in a sound about six feet deep near Atlantic City, N. J.

Clymena Torquatus, Leidy. Body cylindrical, with a membranous collar at the fifth segment. Head abruptly truncated, concave, with a thin membranous border emarginate below and on each side. Mouth inferior, at the summit of a double-ringed papilla. Length? (the posterior portion of the only specimen found is either wanting or the body terminates very abruptly). The anterior fourteen segments measure one inch and a half in length by one line in breadth. Found with the preceding species.

Pectinaria Auricoma, Grube. (*P. Belgica*, Grube, Gould; *P. Groenlandica*, Grube, Stimpson)? Body composed of nineteen segments, including the head and tail. Paleæ eight to sixteen in a fasciculus, according to age. Twenty-eight denticulations to the

frontal border. Length up to an inch and a half. Point Judith and Great Egg Harbor.

Terebella Ornata, Leidy. (Pl. XI, figs. 44, 45). Body with about one hundred segments, of which forty-five are setigerous. The anterior ten ventral plates transversely oblong square, those succeeding abruptly diminished in size. Tentaculae numerous; branchiae in three pairs. Color brownish red. Length to four inches. Lives in tubes of mud. Found at Point Judith, Atlantic City, and Beesley's point.

I found the young of this species at Point Judith. It had the appearance of that of *Terebella nebulosa*, Mont., represented in fig. 24, pl. 3, of M. Edward's Rech. Anat. et Phys., etc. The single specimen obtained was three lines long. There were twelve tentaculae twenty-five eyes around the head, and twenty-eight segments to the body, of which sixteen were setigerous.

Spirorbis Spirillum, Lamarck. On *Chondrus crispus*, Point Judith.

Torquea, Leidy. Body cylindrical, narrowed at the extremities. Tentaculae numerous, attached laterally to the head, capable of very great extension and contraction by the passage to and fro of blood corpuscles from the cavity of the body. Eyes none. Setæ in two rows, three to twelve in a fasciculus, extremities lanceolate. Podal hooks in two rows, short, from twelve to forty in each transverse series, supported at the edge of a laminar process stiffened with fine, simple setæ.

Torqua Eximia, Leidy. (Pl. XI, figs. 51, 52). Body soft, blood red. Tentaculae very numerous, capable of very great extension by the propulsion into them of the bright red corpuscles, with which the cavity of the body is filled. Setæ anteriorly in fasciculi of twelve, posteriorly from three to six. Podal hooks commencing at the eighth segment, from twelve to forty in each series. Worm half an inch to an inch in length, with from forty to sixty segments. Obtained from mud and sand below low-tide mark. Point Judith.

This worm is remarkable for its softness, its blood red color, its numerous extensible tentacles, and its numerous podal hooks. It is capable of slowly progressing by means of its tentaculae. In the process, these are extended by having forced into them the bright red corpuscles which fill the visceral cavity of the body: they then attach themselves by their extremities to the surface upon which the animal is lying, and by subsequent contraction the body is dragged after them.

Cirrhatulus Fragilis, Leidy. (Pl. XI, figs. 39-43.) Body cylindrical, narrowed towards the extremities, reddish orange color, pos-

teriorly greenish. Mouth inferior, circular; upper lip conical. Eyes two. Cirri numerous, orange colored; the first pair commencing at the second setigerous segment and the most robust. Setæ in two rows, simple, in fasciculi of three to five. Podal hooks in two rows, five to eight in each faciculus, sigmoid, bifid at the free extremity. Intestine cylindrical, constricted. Ovaries on each side of the intestine, extending four-fifths the length of the body. Worm three lines long by one-fourth of a line broad, and composed of forty annulations. Found under stones on the shores of Point Judith.

Lumbriconereis Splendida, Blainville. Body cylindrical, copper red and strongly iridescent. Upper lip conical; mouth round, with a short proboscis armed with an inferior pair of dental plates, as well as a complex dental apparatus above and within. Eyes four. Caudal segment furnished with a pair of minute cirri. Lateral tubercles with from six to ten setæ in two fasciculi. Setæ simple, distally curved and grooved and ending in a subulate point. Length up to eighteen inches, with as many as 420 segments. Raked from oyster beds in Great Egg Harbor, N. J., where it is abundant. The animal corresponds closely with De Blainville's description of a specimen, the country of which he remarks he did not know.

Eunice Sanguinea, Montagu. Body compressed, cylindroid, brownish red, iridescent. Head with two oval dorsal lobes. The five antennæ nearly equal. An eye situated between the outer two antennæ. Branchiæ blood red, commencing at the sixteenth segment and continuing until within about forty segments of the posterior extremity. Setigerous tubercles of the anterior sixteen segments containing two spines, the remainder containing four. Setæ in two fasciculi to each tubercle, simple and compound, the latter consisting of a scalpel-like blade received into a forked handle. Length to five inches, with two hundred and twenty segments. Found with the preceding.

Glycera Americana, Leidy (Pl. XI, figs. 49, 50). Body cylindrical, brownish red. Upper lip short with hardly perceptible antennæ. No branchial appendages except three minute dorsal papillæ upon the pinnæ, the latter fine lobed, armed with two spines and four fasciculi of simple and compound setæ, thirty to forty in number in each pinnæ. Simple setæ linear, armed; compound setæ composed of a furcate handle and a long linear lanceolate blade. Length up to five inches, with a breadth of one and a half lines, and about 240 setigerous segments, between each of which is a secondary ring. Found at Point Judith, Atlantic City, and Great Egg Harbor. It

is most like the *Glycera capitata* Oersted, but nevertheless is a different species.

Nereis Denticulata, Stimpson. Abundant at Point Judith, R. I., and on the shores of Great Egg Harbor, N. J.

Siphonostonum Affine, Leidy. Body cylindro-fusiform minutely papillated, with four rows of fasciculi of setæ, those of the anterior three segments directed forward, those of the first segment one-third of an inch long, those of the third segment one line long. Length to three inches, by two lines broad, with 80 segments. Obtained by Mr. Ashmead, from Beesleys Point, N. J.

Lepidonote Armadillo, Leidy. (*Aphrodita armadillo* Bosc. *Lepidonote punctata* Oersted, Stimpson. *Polynæ squamata*, M. Ed. Gould) ? (Pl. XI, fig. 54.) Body of twenty-four segments, with twelve pairs of elytræ completely covering the back. Elytræ fringed externally spotted with variously colored papillæ. Head round with two pairs of eyes, three anterior tentaculæ and three lateral tentaculæ; the middle of the anterior and the first of the lateral tentaculæ the longest, the former with two eye-like black spots, the latter with none. All the others with a single black eye-like dilatation or spot. Dorsal and anal cirri with black eye-like dilated spots. Length an inch and a quarter, by three lines wide. Point Judith and Great Egg Harbor.

The *Lepidonote squamata* is described as having five tentaculæ; in *L. armadillo* I in no case could find less than nine, as represented by figure 54.

Sigalion Mathilda Audet, Edw. (Pl. XI, fig. 53.) Body composed of over 200 segments with over 150 pairs of elytræ completely covering the back. Head with five antennæ, of which the outer ones are the longest and most robust. The middle one is next in length, and the second is the shortest. Eyes four, those anterior nearly concealed by the bases of the second antennæ. Setæ of the dorsal pinnæ simple, those of the ventral pinnæ compound. Length over five inches, by two and a half lines in breadth. Described from a specimen, with the posterior extremity lost. Obtained by Mr. Ashmead at Beesleys Point, N. J.

Ophelia Simplex, Leidy. Body fusiform, above convex, below flattened, anteriorly and posteriorly acute, reddish brown. Mouth inferior, round; cirri commencing at the third and ceasing about the twentieth segment. Setæ in two lateral approximated fasciculi, simple linear. Length two-thirds of an inch, with about 30 setigerous segments. Taken from below low tide at Point Judith.

Lumbriculus Tenuis, Leidy. (Pl. XI, fig. 64.) Body cylindrical, linear, bright red, composed of six or more segments; ninth to the eleventh segment, inclusive, slightly thickened; two generative apertures on each of the ninth segment; four rows of podal hooks, anteriorly five or six in each fasciculus, posteriorly three or four in each fasciculus. Length up to an inch and a half, by the fourth of a line in breadth. Abundant about the roots of grasses on the shores of a sound on Point Judith.

This article is an extract from Marine Invertebrate Fauna on the Coasts of Rhode Island and New Jersey, by Joseph Leidy. Journal Acad. Nat. Sci., 1855.

[January, 1856. No. 154. See Bibliography.]

Dr. Leidy exhibited the heart of a dog, in which the right auricle, right ventricle, and the pulmonary artery and its branches were literally stuffed with worms. Minute worms have long been known circulating with the blood, and termed *Hæmatozoa*. About five years since Dr. L. described, in volume 5 of the Proceedings, the worm exhibited this evening as *Filaria Canis cordis*. The males measure five inches in length, the females ten inches.

Two hearts were brought to Dr. L. by Mr. Jos. Jones, of Georgia; one, that of a pointer, had in it five worms; the other, that of a cur, was the one exhibited. It is probable that both venæ were also filled, as the portions of those vessels that remained were blocked up. The animals did not die from the presence of the entozoa, but were killed in the course of some experiments. The cur was emaciated and voracious, restless when awake, and disturbed in its sleep.

[February, 1856. No. 156. See Bibliography.]

A SYNOPSIS OF ENTOZOA AND SOME OF THEIR ECTO-CONGENERS OBSERVED BY THE AUTHOR.

PROTHELMINTHA.

1. *Bodo Ranarum*, Ehrenberg. Abundant in the intestines of different species of frogs and toads.

2. *Bodo Helicis*, Diesing.

Cryptobia Helicis, Leidy. Proc. Acad. Nat. Sci., iii, 101.

Cryptocicus Helicis, Leidy. Journ. Acad. Nat. Sci., 2d ser., i, 67.

Bodo Helicis, Diesing, Leidy. Pr. A. N. S., v, 284.

3. *Bodo Colubrorum*, Hammerschmidt. In the cloaca of *Tropidonotus sirtalis*.

4. *Bodo Julidis*, Leidy. Pr. A. N. S., v, 100; Trans. Am. Phil. Soc., 2d ser., x, 244.
5. *Bodo Muscarum*, Leidy. Frequent in the intestine of the house fly, *Musca domestica*, in immense quantity.
6. *Bodo Melolonthae*, Leidy. Body spherical; diameter .00449 to .0112 mm. Tail simple, about the length of the diameter of the body. Found in the intestine of *Melolontha quercina* and *M. brunnea*.
7. *Bursaria Intestinalis*, Ehrenb. In the intestine of *Rana pipiens*.
8. *Leucophrys Stryatis*, Dujardin; *Leucophrys*, Leidy. Journ. A. N. S., 2d ser., ii, 49. In the liquids of the body of *Enchytracus*.
9. *Leucophrys Clavata*, Leidy. Journ. A. N. S., 2d ser., ii, 50; iii, 144. Found in the *Lumbriculus limosus* and *L. tenuis*.
10. *Leucophrys Cochleariformis*, Leidy. Journ. A. N. S., 2d ser., iii, 144. Found in the intestine of *Lumbriculus tenuis*.
11. *Leucophrys Socialis*, Leidy. Cordate, ovate, oval, pyriform, or globular, contractile, active, with one or many internal vacuoles; striated, ciliated. Length .036 to .045 mm., breadth .03 mm. Found very frequently and abundantly within the stomach of the remarkable bryozoan, *Urnatella gracilis*. (Pr. A. N. S., vii, 191.)
12. *Nyctotherus Uclav*, Leidy. Pr. A. N. S., v, 233; Trans. Am. Phil. Soc., 2d ser., x, 244. From the large intestine of *Julus marginatus*.
13. *Nyctotherus Ovalis*, Leidy. Pr. A. N. S., v, 100; Trans. Am. Phil. Soc., 2d ser., x, 244. From the intestine of the common cockroach, *Blatta orientalis*.
14. *Albertia? Pellucidus*, Leidy; *Anelodiscus pellucidus*, Leidy. Pr. A. N. S., v, 287.

MYZELMINTHA.

15. ? *Monostomum Incommodeum*, Leidy. Body compressed, above convex, below concave, sides parallel, anteriorly convex, posteriorly angularly convex. Head continuous with the body, obliquely truncated. Mouth round, surrounded with a wide circular lip, which is emarginate below. Male generative aperture? communicating with a hemispherical cavity (acetabulum?) one-fourth the length of the body from the head. Length 9 lines, breadth $1\frac{1}{2}$ lines.

Five specimens were obtained from the fauces of the *Alligator mississippiensis*, in Florida, by Prof. J. W. Bailey, of West Point. Is it probably a species of *Distomum*, with the ventral acetabulum emersed within the body?

16. *Monostomum Ornatum*, Leidy. Body slightly compressed ovoidal, anteriorly broad; yellow variegated with brownish red.

Mouth infero-terminal, acetabuliform, transversely oval. Penis conical, protruding a short distance below the mouth. Female aperture a short distance below the penis. Length 1 to $1\frac{1}{2}$ lines, breadth $\frac{1}{2}$ to $\frac{3}{4}$ ths of a line, thickness $\frac{1}{4}$ th to $\frac{1}{2}$ a line.

A dozen specimens were obtained from the abdominal cavity of *Rana pipiens*.

17. *Monostomum Renicapite*, Leidy. Body depressed, lateral margins parallel, anteriorly and posteriorly rounded, above convex, below concave. Head formed by a transverse, reniform callosity. Mouth transversely crescentic, surrounded with a double lip. Penis a small conical tubercle. Length from $\frac{1}{2}$ an inch to 1 inch, breadth $1\frac{3}{4}$ lines.

Numerous specimens were obtained by Prof. Agassiz from the intestine of *Sphargus coriacea*.

18. ? *Monostomum Molle*, Leidy. Body depressed, elongated elliptical, posteriorly convex. Head? Mouth? Length 9 lines, breadth 2 lines.

I have found two specimens of what I suspect to be a species of *Monostomum* in the lungs of two individuals of *Sternotherus odoratus*. The species is so soft that in the removal of the specimens I mutilated both, and since then I have been unable to find others.

19. *Distomum Lancolatum*, Melilis. Reported to exist in the sheep, *Capra aries*; the ox, *Bos taurus*; the hog, *Sus scrofa*. Stated to be frequent in the sheep in several of the Western States.

20. *Distomum Hepaticum*. In the hepatic ducts of the *Cervus virginianus*. Though I have never seen specimens from the source given, yet I think there is little doubt of its existence, from the circumstance that sportsmen and hunters have frequently informed me they had seen leeches in the liver of the deer, which they supposed the animal had swallowed in drinking. Also reported to exist in the ox, *Bos taurus*, and in the horse, *Equus caballus*.

21. *Distomum Variabile*, Leidy. Var. *a*. Body white, variegated with black in the course of the oviduct, clavate, posteriorly obtuse, minutely echinatated. Neck long, narrow, cylindrical, echinatated. Oral and ventral acetabula nearly equal; the latter one prominent, situated at the base of the neck. Length to 6 lines; breadth of body $\frac{1}{2}$ line.

Var. *b*. Body flattened ovate, continuous with the head anteriorly narrowed, posteriorly obtuse, color and echination as in the preceding variety. Length $2\frac{1}{2}$ lines, breadth 2 lines.

Variety *a* is found attached to the sides of the cavity of the lungs of *Tropidonotus sipedon*, singly or in groups up to six, with the head

and neck buried in tumors, as in the case of the attachment of Echinorhynchi. Variety *b* is found detached in the mucus of the lungs and trachea. Common; obtained in December, when the water snakes were hibernating.

22. *Distomum Horridum*, Leidy; *Distoma horridum*, Leidy. Journ. A. N. S., 2d ser., i, 303. From the excretory duct of the kidneys of the boaconstrictor.

23. *Distomum Variegatum*, Rud.; Leidy. Pr. A. N. S., v, 207. From the lungs of the *Rana pipiens*.

24. *Distomum Retusum* Dug. Leidy, Pr. A. N. S., v, 207. From the intestine of *Rana halcina*.

25. *Distomum Cygnoides* Zeder. Leidy, Pr. A. N. S., v, 207. From the urinary bladder of *Rana pipiens*, *R. Palustris*, *R. halcina*; *Salamandra maculata*, *S. rubra*, *S. salmonica*.

26. *Distomum Longum* Leidy. Pr. A. N. S., v, 206. From the mouth of *Esox estor*.

27. *Distomum Terrestricolle* Rud. Leidy, Pr. A. N. S., v, 206. From the stomach of *Esox reticulatus*.

28. *Distomum Incivile*, Leidy. Body flat, elongated elliptical; echinated between the oral and ventral acetabula, which are equal, and the latter one is hemispherical and sessile. Length $2\frac{1}{2}$ to 3 lines, breadth, 3-5ths to 4-5ths of a line. Obtained from the intestine of *Leiostomus obliquus*.

29. *Distomum Clavatum?* Rud. Body pyriform, transversely annulated, plicated. Neck curved conical, 3 lines long. Ventral acetabulum oblique, prominent, at the base of the neck, 3 lines in diameter, with a circular aperture much larger than the mouth. Length 1 inch, breadth 4 lines. One specimen in the collection of the Academy. Locality unknown.

30. *Distomum Vagans* Leidy.

Distoma helicis Leidy. Pr. A. N. S., iii, 220.

Distomum pericardium, Creplin. Arch. f. Naturg. xv, 78.

Distoma vagans, Leidy. Journ. A. N. S., 2d ser., i, 304.

Cercariacum helicis alternatae, Diesing. Rev. d. Cerc., 24.

Cercariacum vagans, Diesing. Rev. d. Cerc., 24.

Found in *Helix alternata* and in *H. albolabris*.

CLINOSTOMUM, LEIDY.

Head shorter than and separated from the body by a lateral constriction opposite the ventral acetabulum, compressed semi-oval. Body compressed oval. Mouth anterior. Ventral acetabulum large, hemispherical, immersed within the commencement of the body and

having a truncated conical aperture with the apex posterior. A terminal pore to the body.

31. *Clinostomum Gracile*, Leidy. Head semi-ovoid, anteriorly obliquely truncated. Mouth transversely oval, with a prominent margin and a second border, which is slightly emarginated below. Body compressed oblong, oval, convex above, concave below, obtuse posteriorly, acetabulum larger, immersed between the head and body. Length to 3 lines, breadth to 1 line.

Found in the intestine of *Esox* and within cysts in the gills, fins, and muscles of *Pomotis vulgaris*.

32. *Clinostomum Dubium*, Leidy. Head compressed oval, convex anteriorly. Mouth minute, not bordered. Body compressed oblong oval. Ventral acetabulum immersed between the body and head. Length $2\frac{1}{2}$ lines, breadth 2-3ds of a line.

From the intestine of *Rusticola minor*.

33. *Holostomum Cornu*, Nitzsch. Found in the small intestine of *Ardea herodias*.

34. *Holostomum Nitidum*, Leidy. Body divided by a constriction at the anterior third, everywhere echinatated. Head ovoidal. Mouth terminal, round, opening into a cup-shaped pharynx. Body compressed oblong oval, variegated white with yellow. Length to $1\frac{1}{2}$ lines, breadth 2-5ths of a line.

Two specimens were obtained from the small intestine of *Rana pipiens*.

35. *Diplodiscus Subclavatus*, Diesing. Found in the intestine of *Rana pipiens*.

36. *Diplostomum Cuticula*, Diesing. Head elongated elliptical, excavated inferiorly, obtusely angular, much longer than the body. Mouth small, round, pharynx oval, gizzard oval. Generative apertures hemispherical, situated just posterior to the middle. Body ovoid, with a terminal excretory pore. Length from 1-5th to 1-3d of a line. Contained in oval sacs about $\frac{1}{2}$ a line in length.

Found in great number in the liver of *Pomotis vulgaris*.

37. *Aspidogaster Conchicola*, Baer. Leidy, Pr. A. N. S., v, 224.

38. *Malacobdella Grossa*, Blain. Leidy, Pr. A. N. S., v, 209.

CEPHALOCOTYLEA.

39. *Cysticercus Pasciolaris*, Rud. Common in the liver of the rat, *Mus decumanus*.

40. *Cysticercus Cellulosae*, Rud. Occasionally in the muscles of the hog, *Sus scrofa*.

41. *Cysticercus Tenuicollis*, Rud. Occasionally in the liver of the hog, *Sus scrofa*, and in the mesentery of the sheep, *Capra aries*.

42. *Cysticercus Elongatus*, Leuck. In cysts, in the peritoneum of the European domestic rabbit, *Lepus cuniculus*.

43. *Echinococcus Granulosus*, Rud. *Echinococcus polymorphus*, Diesing. From a cyst of about three inches in diameter, between the muscles in the right side of the abdomen, in an English sailor boy : and also in two large cysts in the liver of a Frenchman. I have never met with this parasite in the Anglo-American. In three large cysts in the liver of a large species of monkey (species unknown) : the specimen being preserved in the collection of the University.

44. *Cenurus Cerebralis*, Rud. In the sheep, *Capra aries*.

45. *Tænia Solium*, Lin. Leidy, Pr. A. N. S., ix, 443.

46. *Tænia Laticephala*, Leidy. Ibidem.

47. *Tænia Serrata*, Goeze. Ibidem.

48. *Tænia Cucumerina*, Bloch. Ibidem.

49. *Tænia Elliptica*, Batsch. Ibidem.

50. *Tænia Crassicollis*, Rud. Ibidem.

51. *Tænia Pusilla*, Goeze. Ibidem.

52. *Tænia Pectinata*, Goeze. Ibidem.

53. *Bacillaris*? Goeze. Ibidem.

54. *Tænia Pestifera*, Leidy. Ibidem.

55. *Tænia Strigis Acadiae*. Ibidem, 444.

56. *Tænia Variabilis*? Rud. Ibidem.

57. *Tænia Dispar*, Goeze.

Tænia pulchella, Leidy. Pr. A. N. S., v, 241.

Tænia dispar, Goeze. Leidy, Pr. A. N. S., ix, 444.

58. *Tænia Lactea*, Leidy. Pr. A. N. S., ix, 444.

59. *Tænia Gibbosa*, Leidy. Ibidem.

60. *Dibothrium Punctatum*, Rud. Leidy, Pr. A. N. S., ix, 444.

61. *Sparganum Reptans*, Diesing.

Ligula reptans, Diesing. Syst. Helm., i, 581.

Ligula tritonis, Leidy. Pr. A. N. S., v, 96.

Sparganum affine, Diesing. Verth. d. Cephalocot., 20.

62. *Dibothriorhynchus Abditus*, Leidy. Head continuous with the neck, apex convex and emarginate. Bothria 2, lateral continuous above, oval, with the lateral margins involute. Proboscides filiform, projecting $1\frac{1}{4}$ lines from the head. Neck tæniaform, widening posteriorly. Body constricted from the neck, narrower and longer, tæniaform, narrowing posteriorly and ending in an obtusely angular extremity. Length of head and neck 6 lines, breadth posteriorly 1 line; length of body 7 lines, breadth 3-5ths of a line.

Four specimens were found in a large cream-colored liver, which had been left upon a stall in our fish market. I could not ascertain the species of fish from which it was obtained, but I suspect it to be the halibut, *Hippoglossus vulgaris*. Each worm was closely coiled up at the bottom of a long clavate sac, which was composed of three distinct membranes. The first membrane adhered to the structure of the liver in which it was embedded, beneath the peritoneum. The second membrane was transparent, crisp, and shining. The third one was milk-white, soft, and contractile, and it presented a delicate, tortuous white opaque line extending the length on each side. After opening the third membrane, beneath water, the worm gradually crept out of its own accord.

63. *Pentastomum Subcylindricum*, Diesing; *Pentastomum Didelphidis virginianæ*, Leidy. Pr. A. N. S., v, 96. In cysts of the liver of the opossum, *Didelphis virginiana*.

64. *Pentastomum Euryzonum*, Diesing. In the liver of *Cynocephalus porcarius*.

65. *Pentastomum Proboscideum*, Rud. In the lungs of the Boa-constrictor.

66. *Pentastomum Gracile*, Diesing. Body sub-clavate, incurved, most narrowed anteriorly, annular, not plicated, with the margins of the annuli microscopically denticulated. Head obtuse, bothria subterminal, elevated, each with two hooks, of which the upper one is the smaller. Mouth elevated, conical, in the focus of the semicircle formed by the bothria. Length from 3 to 4 lines, breadth $\frac{1}{3}$ d of a line.

Eleven specimens were obtained by Jos. Jones from the stomach of the *Alligator mississippiensis*.

RHYNGODEA.

67. *Gregarina Juli Marginati*.

Gregarina larvata, Leidy. Pr. A. N. S., iv, 232.

Gregarina juli marginati, Leidy. Trans. Am. Phil. Soc., 2d ser., x, 237.

68. *Gregarina Juli Pusili*, Leidy. Trans. Am. Phil. Soc., 2d ser., x, 238.

69. *Gregarina Polydesmi Virginica*. Ibidem.

70. *Gregarina Passali Cornuti*. Ibidem.

71. *Gregarina Acheta Abbreviatæ*. Ibidem.

72. *Gregarina Locusta Carolinæ*. Ibidem, 239.

73. *Gregarina Blattarum*, Siebold; *Gregarina blattæ orientalis*, Leidy. Trans. Am. Phil. Soc., 2d ser., x, 239.

74. *Gregarina Scarabei*, Relicti.*Gregarina*. Leidy, Pr. A. N. S., v, 208.*Gregarina scarabei relicti*. Leidy, Pr. A. N. S., v, 287.

75. *Gregarina Melalonthæ*, Brunneæ. Body oblong oval; head oblate spheroidal, slightly elevated at the summit. Single and in pairs. Length of body .405 mm., breadth .252 mm.; length of head .108 mm., breadth .144 mm.

Found in the intestine of *Melalontha brunnea*.

76. *Gregarina Nereidis Denticulatæ*. Leidy, Journ. A. N. S., 2d ser., iii, 144.

77. *Echinorhynchus Ovatus*, Leidy. Pr. A. N. S., v, 97 (1850).

Echinorhynchus campanulatus, Diesing. Syst. Helm., ii, 21 (1851). From the small intestine of *Felis Leopardus*.

78. *Echinorhynchus Gigas*, Goeze.Small intestine of the hog, *Sus scrofa*.77. *Echinorhynchus Microcephalus*, Rud.*Echinorhynchus tortuosus*, Leidy. Pr. A. N. S., v, 97.Found in the mesentery of *Didelphis virginiana*.

80. *Echinorhynchus Striatus*, Goeze. Body cylindro-clavate, anteriorly minutely echinated. Proboscis obovate, with 12 to 15 circles of hooks. Neck short, conical, unarmed. Length to 10 lines; breadth anteriorly 1½ lines. Color, orange.

Several specimens were obtained by Joseph Jones from the intestine of *Tantalus loculator*.

81. *Echinorhynchus Manifestus*, Leidy.

Echinorhynchus pici colaris. Leidy, Pr. A. N. S., v, 98. Body slightly compressed cylindroid, most dilated anteriorly, obtuse posteriorly, transversely corrugated. Proboscis subpyriform, with the rounded apex armed with 3 or 4 rows of hooks. Neck a simple linear constriction. Length 8 lines to an inch.

Several specimens were found in the intestine of *Picus colaris*.82. *Echinorhynchus Hamulatus*, Leidy.

Echinorhynchus cmydis. Leidy, Pr. A. N. S., v, 207. Body long, white, sub-clavate, curved. Proboscis sub-globular, with a single row of strong hooks and a few rudimental hooklets. Length 2 to 14 lines, breadth to ⅓ of a line.

Frequent in the intestine of *Emys geographica*, *E. insculpta*, *E. guttata*, and *E. serrata*. From several individuals of the latter species Mr. Joseph Jones obtained more than a hundred specimens.

83. *Echinorhynchus Acus*, Rud.Intestine of *Morrhua americana*.

84. *Echinorhynchus Proteus*, Westrumb. Pr. A. N. S., v, 208.

Intestine of *Labrax lineatus*.

85. *Echinorhynchus Globulosus?* Rud.

Echinorhynchus lateralis, Leidy. Pr. A. N. S., v, 207. Body subfusiform, most narrowed posteriorly. Proboscis cylindrical, projecting laterally, furnished with 12 to 14 rows of hooks. Neck very short. Length to one inch, breadth to two-fifths of a line.

Intestine of *Salmo fontinalis*: obtained by Prof. Baird and Prof. Agassiz.

86. *Echinorhynchus Angustatus?* Rud.

Echinorhynchus socialis, Leidy. Pr. A. N. S., v, 156. Body cylindroid, narrowing posteriorly, frequently dilated anteriorly. Proboscis cylindrical, with 26 rows of hooks. Neck very short, conical, unarmed. Length from 6 lines to $2\frac{1}{4}$ inches, breadth to 2-3ds of a line.

Frequent in the intestine of *Platessa plana*.

NEMATOIDEA.

87. *Trichina Spiralis*, Owen.

Occasional in the Anglo-American.

88. *Trichina Affinis*, Diesing.

Trichina spiralis, Owen. Leidy, Pr. A. N. S., iii, 108.

Observed in the muscles of the hog, *Sus scrofa*.

89. *Anguillula Aceti*, Ehrenberg.

Common in ordinary cider vinegar.

90. *Anguillula Glutinis*, Ehrenberg.

Common in paste of wheat, rye, tragacanth, etc.

91. *Anguillula Socialis*, Leidy.

Oxyuris socialis, Leidy. Pr. A. N. S., v, 102.

Found in the intestine of the black cricket, *Acheta abbreviata*.

92. *Anguillula Longa*, Leidy. Pr. A. N. S., v, 225.

Found in ditches near Philadelphia.

93. *Anguillula Fossularis*, Leidy. Pr. A. N. S., v, 226.

Found in stagnant ponds near Philadelphia.

94. *Amblyura Serpentulus?* Hemp. et Ehrenb.

Anguillula longicauda, Leidy. Pr. A. N. S., v, 225. Mouth with cirri (error in the previous observation and description). Tail long, subulate; suectorial disk exceedingly minute, clavate. Length to one-fortieth of an inch.

Common about gutters and water-spouts in Philadelphia.

95. *Hystrignathus Rigidus*, Leidy. Pr. A. N. S., v, 102; Flora and Fauna within Liv. An., 44.

PONTONEMA, LEIDY.

Body capillary, narrowing toward the extremities. Head continuous with the body, truncated and surmounted with angular papillæ ciliated. Eyes none. Tail obtuse. Generative aperture ventral, near the middle of the body. Oesophagus long, cylindro-clavate; gizzard none, intestine straight, capacious; anus ventral and posterior.

96. *Pontonema Vacillatum*, Leidy. Jour. A. N. S., 2d ser., iii, 144. Body cylindroid, anteriorly with longitudinal rows of short cirra in addition to those of the head; posteriorly incurved; tail short, thick, conical, obtuse. Length to 9 lines, breadth to one-fifth of a line.

Found on the seashore of Rhode Island, beneath stones, between tides.

97. *Pontonema Marinum*, Leidy. Jour. A. N. S., 2d ser., iii, 144. Body cylindroid; head convex; mouth surrounded with angular papillæ. Cirra 4, at the side of the head. Tail long, narrow, conical, obtuse. Length to 3 lines.

Found at the bottom of a sound on the coast of New Jersey.

POTAMONEMA, LEIDY.

Body filiform, narrowing towards the extremities. Head continuous with the body, slightly dilated, obtuse. Mouth large, infundibuliform, unarmed; oesophagus narrow, flexuous, membranous, gradually expanding into a capacious, straight, cylindrical intestine; anus none? or exceedingly indistinct. Caudal extremity obtuse. Generative aperture of the female near the middle of the body.

98. *Potamonema Nitidum*, Leidy. Body cylindroid, most narrowed anteriorly. Head without appendages. Caudal extremity broad, obtusely conical. Length 5 lines, breadth one-fifth of a line.

An active wriggling, glistening white worm, found among beds of *Ualisneria americana* growing in the river Schuylkill, near Philadelphia.

NEMA, LEIDY.

Body ascaridiform. Head without appendages. Mouth unarmed, large, infundibuliform, oesophagus tubular, membranous, expanding into a simple straight intestine; anus ventral. Tail conical, acute, recurved. Generative aperture near the middle of the body.

99. *Nema Facilans*, Leidy. Body white, glistening. Length $1\frac{1}{2}$ millimeters, breadth .050 mm. Tail .115 mm. long.

An active wriggling worm, found about some dead specimens of a black *Phryganæa*, which was infested with a fungus parasite, and attached to stones at the water's edge of a small brook near Philadelphia.

100. *Streptostomum Agile*. Pr. A. N. S., iv, 230; v, 285; Flora and Fauna within Liv. An., 45.

Aorurus, Leidy. Pr. A. N. S., iv, 230; v, 284.

101. *Streptostomum Gracile*, Leidy. Pr. A. N. S., iv, 100; v, 285; Flora and Fauna, 46.

In parte *Oxyuris Diesingii*, Hammerschmidt. Isis, 354 (1848).

In parte *Oxyuris blattæ orientalis*, Hammerschmidt. Naturw. Ab. v. Haid., i, 284.

In parte *Anguillula macrura*, Diesing. Syst. Helm., II, 134.

102. *Thelastomum Attenuatum*, Leidy. Pr. A. N. S., v, 101; ib., 285; Flora and Fauna within Liv. An., 46.

Aorurus, Leidy. Pr. A. N. S., iv, 230; v, 284.

103. *Thelastomum Appendiculatum*, Leidy. Pr. A. N. S., v, 101; ib., 285; Flora and Fauna, 47.

In parte *Oxyuris blattæ orientalis*, Hammerschmidt. Naturw. Ab. v. Haid., i, 284.

In parte *Anguillula macrura*, Diesing. Syst. Helm., II, 134.

104. *Thelastomum Labiatum*, Leidy. Pr. A. N. S., v, 101; ib., 285; Flora and Fauna, 47.

105. *Thelastomum Robustum*, Leidy. Pr. A. N. S., v, 101; ib., 285; Flora and Fauna, 48.

Thelastomum brevicandatum? Leidy. Pr. A. N. S., v, 208; ibidem.

106. *Thelastomum Ventustum*, Leidy. Body of female fusiform, straight, with the tail long, narrow, conical, straight, acute. Body of male incurved, with the tail short, depressed, ending in a recurved subulate point, and having a pair of oblong lobes or alæ, extending the length ventrally. Generative and anal apertures terminating together abruptly. Penis a curved, conical, acute spiculum. Length of female to $2\frac{1}{2}$ lines, breadth to one-fifth of a line; length of male to 1 line, breadth 1-6th of a line.

Found in great number within the large intestine of *Testudo polyphemus*. Obtained by Mr. Joseph Jones in Georgia. It is a singular fact that this species is infested with vegetable parasites, as in the case of those found in myriapods and insects.

107. *Iscaris Vermicularis*, Lin.

This species is the most common of all the parasitic worms in the Anglo-American.

108. *Ascaris Lumbricoides*, Lin.

This species is the second of the most common of parasitic worms in the Anglo-American.

In the University Museum there is a preparation of the liver of a boy in which a number of individuals of this worm have forced themselves into the divisions of the hepatic duct.

Frequent also in the small intestines of the hog, *Sus scrofa*.

109. *Ascaris Leptoptera*, Rud.

Ascaris felis discoloris, Leidy. Pr. A. N. S., v, 155.

Found in the small intestine of the panther. *Felis concolor*.

110. *Ascaris Mystax*, Rud.

Common in the domestic cat, *Felis catus*.

111. *Ascaris Marginata*, Rud.

Frequent in the dog, *Canis familiaris*.

112. *Ascaris Columnaris*, Leidy.

Ascaris alienata, Rud. Leidy, Pr. A. N. S., v, 205. Body very uniformly cylindrical until within a short distance of the extremities. Head naked; lips prominent. Tail short, conical, obtuse, in the male incurved. Length of female 4 inches, breadth $1\frac{1}{4}$ lines: length of male 2 inches, breadth $\frac{1}{2}$ a line.

Two specimens, male and female, were found in the intestine of *Mephitis chinga*.

113. *Ascaris Levis*, Leidy. Body cylindrical, narrowing at the extremities. Head naked; lips prominent. Tail conical, mucronate. Length of female $3\frac{1}{2}$ inches, breadth $1\frac{1}{2}$ lines. Male not seen.

A single specimen was obtained by Mr. Packard from the intestine of *Arctomys monax*.

114. *Ascaris Tentaculata*, Rud. Found in the intestine of *Didelphis virginiana*.

115. *Ascaris Vesicularis*, Frolich. Common in the cœcum of the turkey, *Meleagris gallopavo*, and of the fowl, *Phasianus gallus*.

116. *Ascaris Intlexa*, Rud. Common in the small intestine of the fowl *Phasianus gallus*.

117. *Ascaris Serpentulus*, Rud. One female, $1\frac{1}{2}$ inches long, was obtained by Mr. Schafhirt from the intestine of *Ardea violacea*.

118. *Ascaris Longa*, Leidy. Body most narrowed anteriorly, and only slightly so at the posterior fourth. Head naked, subacute; lips slightly prominent. Tail obtusely rounded, with the anus forming a transverse, subcrescentic fissure nearly at its extremity. Length of the female 9 inches, breadth $1\frac{1}{2}$ lines. Male not seen.

A single specimen was obtained by Mr. Joseph Jones from the intestine of *Tantalus loculator*, in Georgia.

119. *Ascaris Tenuicollis*, Rud. Frequent in the stomach and intestine of the *Alligator mississippiensis*.

120. *Ascaris Anoura*, Dujardin. Eight specimens were obtained from the intestine of *Cobræ constrictor*. The females measure up to 6 inches in length by 1 line in breadth; the males $3\frac{1}{2}$ inches in length by $\frac{3}{4}$ of a line in breadth. Six specimens, apparently of this species, were sent to me by Prof. Agassiz. They were obtained, with nearly a pint of others, from the intestine of the boaconstrictor. I do not feel positive that they are really of the same species, as the specimens are too badly preserved to ascertain the fact correctly; but the size and details of form agree pretty closely.

121. *Ascaris Nuda*, Leidy. Body most narrowed anteriorly. Head naked, with the epidermis closely adherent; lips large, oblong. Tail short, incurved, conical, minutely mucronate. Length of female 2 to $2\frac{1}{2}$ inches, breadth 1-3d to $\frac{1}{2}$ a line. Male not seen.

Two females were obtained from the intestine of *Crotalus adamanteus* by Mr. Schafhirt. Is this probably the same as the last species?

122. *Ascaris Humilis*, Leidy. Body cylindroid, recurved, white. Head obtuse, naked; mouth trilobed, pharyngeal apparatus none; œsophagus pestleform. Tail substraight, conical, acute. Length 2 lines, breadth 1-10th of a line.

Eight specimens were obtained from the lungs of *Tropidonotus sirtalis* in December.

123. *Ascaris Entomelas*, Leidy. Proc. A. N. S., v, 206.

From the lungs of *Rana halcina*.

124. *Ascaris Acuta*, Muller. A single male, 14 lines long and $\frac{1}{3}$ d of a line broad, was obtained from the intestine of *Platessa plana*.

125. *Ascaris Neglecta*, Leidy. Body cylindro-fusiform, most narrowed anteriorly. Head naked; lips large, obtuse. Tail short, conical, acute. Length of female 2 inches, breadth three-fifths of a line; male about half the size.

Twelve specimens were obtained by Prof. Baird from the intestine of *Diodon maculostriatus*.

126. *Ascaris Clavata*, Rud. Head with a linear ridge on each side. Tail short, conical, incurved, mucronate; in the female with a linear ridge extending forward on each side. Length of female to $3\frac{1}{4}$ inches, breadth $\frac{3}{4}$ of a line; length of male to 2 inches, breadth to $\frac{1}{2}$ a line.

Numerous specimens were obtained by Prof. Agassiz from the in-

testine of *Morpha pruinosa*, and I have obtained others from the intestine of *Morpha americana*.

127. *Ascaris Cylindrica*, Leidy.

Angiostomum? cylindricum, Diesing. Syst. Helm., ii, 559.

Ascaris cylindrica, Leidy. Pr. A. N. S., iv, 229. Body cylindroid, equally attenuated towards the extremities, curved. Mouth distinctly trilabiate. Tail narrow, conical, curved, acute. Female generative aperture just posterior to the middle. Length four-fifths of a line, breadth one-twelfth of a line.

Found in the intestine of *Helix alternata*. No cartilaginous pharynx as in *Angiostomum*.

128. *Ascaris Infecta*, Leidy. Pr. A. N. S., iv, 229; Faun. and Flora within Liv. An., 42. Found in the ventriculus of *Julus marginatus*.

129. *Synplecta Pendula*, Leidy. Pr. A. N. S., v, 240. From the stomach of *Emys guttata*.

130. *Oxyuris Compar*, Leidy. Body fusiform; head continuous with the body, subacute, with a dilatation of the epidermis; mouth small. Tail of female long, subulate, spirally contorted; the generative aperture one-fifth the length of the body from the head. Length of female 4 to 7 lines, breadth 1-3d of a line; length of tail from the anus $1\frac{1}{2}$ lines.

Seventeen specimens were found in company with others of *Taenia crassicollis* in the small intestine of the cat, *Felis catus*. Oesophagus long, pestle-form; gizzard globulo-pyriform; intestine dilated at the commencement, afterwards cylindrical. Males were not seen.

131. *Oxyuris Curvula*, Rud. Intestine of the horse, *Equus caballus*.

132. ? *Oxyuris Dubia*, Leidy. Body fusiform, curved. Head continuous with the body, naked. Mouth unarmed. Female generative aperture about the middle of the body. Tail abruptly narrowed, acutely conical. Length of female $1\frac{1}{2}$ lines, breadth 1-4th of a line. Male not seen.

Found in the cæcum of *Bufo americanus* and of *Salamandra rubra*.

SPIRONOURA, LEIDY.

Body cylindroid, attenuated at the extremities. Head continuous with the body. Mouth round, surrounded by a circular papillated lip. Caudal extremity of male spiral acute, tuberculate, with the two spicula of the penis curved, ensiform, costate; of the female

conical, acute, with the generative aperture at the posterior third of the body.

133. *Spironoura Gracile*, Leidy. Body of female incurved; that of male spiral posteriorly. Head naked; mouth with a circular lip of 6 papillæ. Tail of female long, calcareous, acute; of male, with two rows each of three tubercles. Spicula of penis curved ensiform, costate, emarginate at the extremity. Length of female 8 lines, breadth 1-3d of a line; length of male to 4 lines, breadth to 1-8th of a line.

Found in the stomach of *Emys serrata*. Oesophagus long, pestle-form, gizzard globular, commencement of the intestine cordiform, rectum short, wide, pyriform. Ovaries double.

134. *Spironoura Iffine*, Leidy. Body of female curved; that of male posteriorly spiral. Head naked, mouth with a circular lip of 6? papillæ. Tail of female nearly straight, moderately long, conical, acute; of the male, conical, incurved, ensiform, costate, acute. Length of female $4\frac{1}{2}$ lines, breadth one-fifth of a line; length of male 3 lines, breadth 1-6th of a line.

Found in the cæcum of *Cistudo carolina*.

135. *Physaloptera Turgida*, Rud.

Spiroptera didelphidis virginiana, Leidy. Pr. A. N. S., v, 155. Common in the stomach of *Didelphis virginiana*. Found by Dr. Goddard, Mr. Schafhirt, and myself, and also by Mr. Joseph Jones, in Georgia.

136. *Physaloptera Limbata*, Leidy.

Spiroptera scalopis canadensis, Leidy. Pr. A. N. S., v, 156. The mouth bilabiate and surrounded by an elevated linear margin. Alæ of male, each with 4 diverging costæ. The length 6 lines, breadth 1-4th of a line.

137. *Physaloptera Mucronata*, Diesing.

Numerous specimens were obtained by Mr. Joseph Jones from the stomach of the *Alligator mississippiensis*, in Georgia.

138. *Physaloptera Constricta*, Leidy. Body wide, with the brown intestine shining through, cylindrical to within a short distance of the extremities; incurved; anterior extremity with one or two constrictions, and abruptly inflexed. Lips large, lateral, constricted from the body, each trilobate. Tail of female incurved, abruptly conical and acute; of the male alated, with the alæ narrow, long, and turgid. Length of female $1\frac{3}{4}$ inches, breadth two-fifths of a line; male half the size.

Found frequently in the stomach of *Tropidonotus sipedon*, with the anterior extremity of the body hooked through the mucous mem-

brane, and very tightly adhering by means of the one or two constrictions.

139. *Physaloptera Contorta*, Leidy. Body capillary, most narrowed anteriorly, with the posterior four-fifths spirally contorted; white, with the intestine brown. Lips prominent, constricted from the body, trilobate. Tail short, conical, acute; in the male with narrow alæ, each furnished with five funnel-shaped pores. Length of female from 6 lines to one inch; breadth to $\frac{1}{4}$ th of a line; male from one-half to three-fourths the size.

Frequent in the stomach of *Emys serrata*, *Emys reticulata*, *Cistudo carolina*, and *Kinosternum pennsylvanicum*, adhering to the mucous membrane in the same manner as *Physaloptera constricta*.

140. *Physaloptera Abjecta*, Leidy. Body most narrowed anteriorly, incurved. Mouth distinctly bilabiate; lips lateral, prominent. Caudal extremity incurved, obtusely conical. Length 10 lines, breadth $\frac{1}{2}$ a line.

One specimen was obtained by Mr. Joseph Jones, from the stomach of *Psammophis flagelliformis*.

141. *Cheiracanthus Horridus*, Leidy. Body subcylindrical, incurved, posteriorly sub-clavate, obtuse; anteriorly covered with palmate plates, furnished with as many as eight spines, and degenerating posteriorly to single spines. Head oblate-spheroidal, spirally echinate. Mouth bilabiate, with the lips lateral and papillated. Length of female $2\frac{3}{4}$ inches, breadth $1\frac{1}{2}$ lines. Male not seen.

Four specimens were obtained by Mr. Joseph Jones in the stomach of the *Alligator mississippiensis* in Georgia.

142. *Tricocephalus Dispar*, Rud.

Not infrequent in the children of the Anglo-American and also in the negro.

143. *Tricocephalus Minutus*, Rud.

Numerous specimens were obtained by Joseph Jones from the cæcum of *Didelphis virginiana* in Georgia.

144. *Cucullanus Microcephalus*, Dujardin.

Cucullanus trispinosus, Leidy. Pr. A. N. S., v, 240.

Frequent in the stomach and intestine of *Emys guttata*, *Emys reticulata*, *Emys serrata*, and *Chelonura serpentina*.

145. *Cucullanus Roseus*, Leidy. Pr. A. N. S., v, 155. Body fusiform, sub-straight, red, anteriorly obtuse. Tail straight, short, conical, acute. Mouth with a complex corneous apparatus. Upper lip of anus turgid. Penis consisting of two calcareous spiculae. Generative aperture of the female two-fifths the length of the body from

the tail. Length of female to $1\frac{1}{2}$ inches, breadth to three-fifths a line; length of male to 10 lines, breadth $\frac{1}{2}$ a line.

From the intestine of *Testudo* —? from Java.

146. *Sclerostomum Dentatum*, Rud.

Several specimens, male and female, were obtained from the liver of the hog, *Sus scrofa*.

147. *Sclerostomum Syngamus*, Diesing.

Common in the trachea of the common fowl, *Phasianus gallus*.

148. *Sclerostomum Armatum*, Rud.

Specimens preserved in the collection of the Academy and presented by Dr. Harlan, who obtained them from an aneurism of the aorta of the horse, *Equus callabus*. *Strongylus armatus*, Rud. Harlan Med. and Phys. Res., 553.

149. *Strongylus Attenuatus*, Leidy. Body cylindroid, narrowing toward the extremities; female nearly straight, male curved. Head obtuse, bialated; alae long and moderately broad. Mouth with minute angular papillæ. Tail of female straight, conical, acute. Bursa of the male bilobed, multiradiate. Length of female 6 lines, breadth $1\frac{1}{5}$ th of a line; length of male $4\frac{1}{2}$ lines, breadth one-fifth of a line.

Sixteen specimens were obtained by Mr. Schafhirt from the intestine of *Cynocephalus porcarius*.

150. *Strongylus Simplex*, Leidy. Body cylindroid, anteriorly rather abruptly narrowed; female straight; male curved, with the caudal extremity incurved. Head obtusely conical, not alated nor papillated. Tail of female compressed, conical, acute; generative aperture one-third the length of the body from its extremity. Bursa of male trilobed? one lobe posterior and two lateral, multiradiate. Length of female 4 to 5 lines, breadth $1\frac{1}{4}$ th of a line; length of male $2\frac{1}{2}$ to $3\frac{1}{2}$ lines, breadth $1\frac{1}{6}$ th of a line.

Numerous specimens were obtained from the small intestine of *Hystrix dorsata*.

151. *Strongylus Iuricularis*, Zeder. Intestine of *Bufo americanus* and of *Cistudo carolina*.

152. *Eustrongylus Gigas*, Diesing. Frequent in the kidneys of the mink, *Putorius vison*, and occasionally occurring in the dog, *Canis familiaris*. One specimen, eight inches long, was obtained by Mr. Joseph Jones from the heart of the latter animal, in association with Filariae, mentioned in another part of this paper.

153. *Trichosomum Lineare*, Leidy. Body filiform, nearly equally narrowed towards the extremities. Caudal extremity of the female spirally involute. Tail incurved, obtuse, with two conical points

on the ventral aspect of the extremity. Caudal extremity of the male spiral; tail long, conical acute; generative aperture a considerable distance from the end of the tail. Length of female 3 inches, breadth 1-6th of a line; length of male $1\frac{1}{2}$ inches, breadth one-tenth of a line.

Seven specimens were obtained from the small intestine of the cat, *Felis catus*.

154. *?Trichosomum Picorum*. Body cylindroid, equally narrowed and acute at the two extremities. Mouth and anus terminal. Length of female 7 lines, breadth one-fifth of a line.

A single specimen was obtained by Mr. Schafhirt from the intestine of *Picus colaris*.

155. *Agamoneema Capsularia*? Diesing. Body slender, most narrowed anteriorly. Mouth small, circular, surrounded by an undivided lip. Tail short, obtusely conical, minutely mucronate. Length 5 to 10 lines, breadth from 1-8th to 1-4th of a line.

Found free in the intestine of *Centropristes nigricans*, *Clupea elongata*, and *Alosa sapidissima*; also free in the intestine and pancreatic cœca of *Morrhua americana*, and larger specimens, 1 inch in length and 1-3d of a line in breadth, coiled up within sacs of the peritoneum in the same fish.

156. *Agamoneema Papilligerum*? Diesing. Body cylindrical, most narrowed anteriorly, posteriorly obtusely conical. Mouth surrounded by four papillæ; anus terminal. Length to $4\frac{1}{2}$ inches, breadth two-fifths of a line.

One specimen was obtained from the abdominal cavity of *Esox*.

157. *Filaria Medinensis*, Gmelin.

Filaria hominis oris? Leidy. Pr. A. N. S., v. 117.

A specimen is preserved in the collection of the Academy, and was recently brought from western Africa by Dr. J. L. Burtt, U. S. N., who obtained it from the leg of a white soldier.

158. *Filaria Papillosa*, Rud.

Intestine of the ox, *Bos taurus*.

159. *Filaria Immitis*, Leidy.

Filaria canis cordis, Leidy. Pr. A. N. S., v. 118. Body cylindrical, obtusely rounded at the extremities. Mouth small, round, unarmed. Caudal extremity of male spiral, with a row of five tubercles, and a narrow ala upon each side. Penis protruding a short distance above the anus. Length of female to 10 inches, breadth to $\frac{1}{2}$ a line; length of male to 5 inches, breadth 1-4th of a line.

Mr. Joseph Jones recently presented to me two specimens of the heart of the dog, in the right ventricle of one of which there were

five of the Filaria just described. In the other specimen the right auricle and ventricle and the pulmonary artery in its ramifications through the lungs are literally stuffed with Filariae. A portion of the blood of this dog, given to me by Mr. Jones, contains a great number of the young of the Filaria.

In relation to the symptoms which accompanied the presence of these worms in the heart of the dogs while living, Mr. Jones has furnished the following notes: The heart containing the five worms was taken from a male pointer dog whose appetite was voracious and insatiable, and notwithstanding he was abundantly supplied with food, he remained in a very lean condition. The heart and lungs containing great numbers of worms was from a cur dog, who was always so thin as to resemble a skeleton, and it was impossible to benefit his condition with the most liberal supply of food. Both dogs were of an exceedingly restless disposition. They did not die in consequence of the presence of the Filariae, but were killed in the course of some physiological experiments.

160. ? *Filaria Dubia*, Leidy. Body cylindroid, narrowed toward the extremities, rolled in a transverse spiral. Head continuous with the body, naked. Mouth minutely papillated. Tail acute. Length 9 lines, breadth 1-3d of a line.

Nine specimens were contained within two globular sacs of the gastric mucous membrane of the albatross, *Diomedea exulans*, the preparation having been obtained in the South Atlantic by Dr. W. S. W. Ruschenberger, U. S. N. The sacs also contained each a brown globular body about $3\frac{1}{2}$ lines in diameter, divided by lines into quarters, intersected by transverse corrugations. At one pole of these enigmatic bodies was an elliptical aperture, and at the opposite pole a small conical tail-like appendage. One of the bodies being cut open, exhibited no regularity of structure. The Filariae were situated between the globular bodies and the walls of the sacs containing them.

161. *Filaria Itteniata?* Rud. Body cylindrical, conical at the extremities. Head convex; mouth round, unarmed. Caudal extremity of male incurved. Tail short, obtusely conical. Length of female 4 inches, breadth 1-3d of a line; length of male 2 inches, breadth one-fifth of a line.

Five specimens were obtained by Prof. Baird from the abdominal cavity of *Sturnella ludoviciana*.

Two female Filariae having the same form as above, 5 inches in length and $\frac{1}{2}$ a line in breadth, were obtained by Prof. Baird from the abdominal cavity of *Colaptes auratus*.

162. *Filaria Bispinosa*, Diesing. *Filariae boæ constrictoris*, Leidy. Pr. A. N. S., v, 118. Found beneath the skin of the boaconstrictor.

163. *Filaria Cistudinis*. Body capillary, spirally involute attenuated at the extremities. Head and tail obtusely rounded. Mouth unarmed. Anus terminal. Length $1\frac{1}{2}$ inches, breadth $1\text{-}6$ th of a line.

One specimen was obtained by Mr. Schafhirt from the heart of *Cistudo carolina*.

164. *Filaria Amphiumæ*. Body cylindroid, attenuated towards the extremities, spirally coiled, anteriorly truncate, posteriorly acute. Length 6 lines, breadth $1\text{-}5$ th of a line.

Numerous specimens were found coiled up in the parietes of the stomach of *Amphiuma means*, the individual of which had been so long preserved in alcohol that the characters of the worms could be partially determined only.

165. *Filaria Nitida*, Leidy. Body filiform. Mouth large, round, unarmed; cesophagus one-fourth of the length of the body; intestine straight, capacious, with a short narrow rectum; anus terminal, with a short tubular prolongation. Tail sub-distinct, conical. Color red. Length to 5 lines, breadth $1\text{-}12$ th of a line.

Found coiled up in oval cysts in the peritoneum and abdominal muscles of the *Rana pipiens*.

166. *Filaria Solotaria*, Leidy. Mouth transverse, sub-elliptical, papillated. Caudal extremity obtusely rounded. Anus terminal. Length to 2 inches, breadth $1\text{-}3$ d of a line.

Coiled up in cysts between the tunics of the stomach and intestines of *Emys serrata* and *Chelonura serpentina*.

167. *Filaria Rubra*, Leidy. Capillary, anteriorly truncated, posteriorly obtusely conical, dark brownish red in color. Mouth transverse, slightly bilabiate; lips papillated. Anus terminal, transverse, crescentic. Length to $4\frac{1}{2}$ inches, breadth $1\text{-}4$ th of a line.

Frequently found in considerable number in the peritoneal cavity of *Labrax lineatus* during the winter.

168. *Filaria Quadrituderculata*, Leidy. Body capillary, red in color, anteriorly conical, unarmed. Mouth circular, with an elevated, non-papillated, circular lip. Caudal extremity incurved, conical, ending in a minute conical papilla, and having on each side a pair of minute tubercles. Length 4 inches, breadth $1\text{-}3$ d of a line.

A single specimen was found by Mr. Schafhirt in the muscles of the back of *Anguilla vulgaris*.

169. *Gordius Varius*, Leidy. Pr. A. N. S., v, 262 (1851).

Gordius aquaticus of American authors.

Gordius tricuspidatus? Seibold. Zeits. F. Wiss. Zoöl., vii, 143 (1855). Body long, linear, cylindrical, attenuated towards the extremities; narrowest anteriorly; passing through a variety of shades from a dusky yellowish white or cream color to a dusky ochreous yellow, yellowish brown, reddish brown, light chocolate to dark chocolate brown, or to ebony black; lustrous, often iridescent in sunlight. Head surrounded by a dark-brown or black ring, obliquely truncated and terminated by a convex, translucent, whitish vesicular membrane, at the lower part of which is a minute round mouth. Integument areolated; areole irregularly pentahedral.

Female.—Lighter in color than the male, and usually much longer and thicker. Caudal extremity trifurcate; caudal lobes elongated, elliptical; one narrower than the other two. Generative aperture round, enclosed by the caudal lobes.

Male.—Usually dark brown, often inclining to black. Caudal extremity curved. Tail bifurcate; caudal lobes curved conoidal, obtuse, divergent. Generative aperture ventral, just above the caudal lobes. Twenty females and twelve males were found in Rancocas creek, a branch of the Delaware, New Jersey, in the month of August. Length of the former 5 to 12 inches; breadth 1-4th to 2-5ths of a line. Length of the latter from 4 to 6 $\frac{1}{2}$ inches; breadth 1-5th to 1-4th of a line. Three females from 7 to 12 inches in length, and from 1-4th to 2-5ths of a line in breadth; and one male 6 $\frac{1}{2}$ inches in length and 1-4th of a line in breadth, were obtained from the Schuylkill river. Mr. Pearsall has given me eight specimens from Philadelphia county. Professor Agassiz has given me a female 12 inches in length from Niagara; a male 6 inches in length and a female 8 inches in length from the vicinity of Cambridge; two females 6 inches in length from Edgartown, and a male 3 inches in length, and two females 4 inches and 9 inches in length from Trenton. Dr. King, of Greensburg, Pa., has given me a male 5 inches in length, from his vicinity. Mr. Hazard, of Point Judith, R. I., has given me a female 10 inches in length by 2-5ths of a line in breadth, from his vicinity. Professor Kirtland has given me a male 5 inches in length, said to have been passed per anum by a girl, near Cleveland, Ohio. Professor Baird has given me three males from the Susquehanna river, near Carlisle, Pa., and a male and female from Lake Champlain, N. Y.

The *Gordius varius* is the most common species of the genus in the United States, and is familiar to most persons under the name of hair-worm, and is erroneously supposed to originate from the maceration of horse hairs in water. The species is remarkably pro-

lific. A single female, 9 inches in length, by 2-5ths of a line in breadth, which I had preserved in a large vessel of water, extruded from between its caudal lobes a cord of ova, broken into segments, the aggregate length of which was 91 inches, and breadth 1-20th of a line. I counted in each transverse disk of the cord about 70 eggs, and in the length of 1-40th of an inch 26 eggs, so that by simple calculation : $70 \times 26 \times 40 \times 91 =$ the whole number of eggs deposited is 6,624,800.

170. *Gordius Aquaticus?* Gmelin.

Gordius seta, Müller. Diesing, Syst. Helm., ii, 83.

Gordius lineatus, Leidy. Pr. A. N. S., v, 263 (1851).

Gordius robustus? Leidy. Ibidem, 275. Body long, filiform, not narrowed anteriorly, dusky yellowish white, cream colored, white, light brown, or dark brown in color, sometimes darker at the extremities, lustrous. Areolæ of the integument hexagonal.

Female.—More robust than the male, opaque, and lighter colored. Head obtusely rounded. Caudal extremity truncated, round.

Male.—Narrower than the female. Head obtusely rounded. Caudal extremity incurved, bifurcated; caudal lobes curved conoidal, obtuse, fimbriated upon the ventral border with simple branching dermal appendages.

Six males from 5 to $7\frac{1}{2}$ inches in length and 1-8th of a line in breadth, and one female 5 inches in length by 1-6th of a line in breadth, of a dusky yellowish white color, were obtained by Professor Baird from a spring in Essex county, New York (*Gordius lineatus*, Pr. A. N. S., v, 263). One female of a light brown color, with the head ringed with black, $3\frac{1}{2}$ inches long by 1-5th of a line broad, procured by Dr. W. S. Gibson from a spring in Philadelphia county. A female of a cream color, with the head ringed with dark brown, $4\frac{1}{2}$ inches long by 1-5th of a line broad, I found in Frederick Brook, at the head of the Bay of Fundy, New Brunswick. A female (*G. robustus*, Pr. A. N. S., v, 275), hardly narrowed at the extremities, brown, rigid, with the head edged with dark brown and the tail slightly expanded, conical, and obtuse, $6\frac{1}{2}$ inches long and $\frac{1}{2}$ a line wide, was obtained by Dr. Charles H. Budd from a boy, who informed him it had crept out of the abdomen of a grasshopper which accompanied the worm. A male and female were obtained by Mr. Schafhirt from a single specimen of *Pterostichus fastidites*, Dejean. The length of each is about 3 inches, the breadth of the male 1-8th of a line, of the female 1-6th of a line.

171. *Mermis Albicans*, Seibold.

Mermis elongata, Leidy. Pr. A. N. S., v, 263.

Mermis crassicaudata, Leidy. Ibidem.

Mermis ferruginea, Leidy. Ib. Body long, capillary, narrowed towards the extremities, most narrowed anteriorly. Head slightly dilated or not at all, truncated, convex. Caudal extremity slightly curved, conoidal, obtuse. Color milk white when the worm is parasitic or is buried in the earth; cream or yellowish white, or light ochreous yellow, or light reddish brown when it lives in water. In alcohol becomes translucent yellow, bright yellow, approaching to orange or brown.

Eleven individuals (*Mermis elongata*, Pr. A. N. S., v, 263), of a dusky yellowish white, and from 6 to 18 inches long by 1-6th to 1-3d of a line broad, were obtained by Dr. Charles H. Budd in the early spring season in a ditch emptying into the Rancocas creek, New Jersey. Six specimens, opaque white in color, from 8 to 15 inches in length, were obtained by Samuel Powell, Esq., in digging in the earth mould of his garden at Newport, R. I. One specimen, of a cream color, 22 inches long and 1-3d of a line broad, was obtained by Dr. William Gibson from a rivulet in Philadelphia county. I found four specimens of a brownish white, from 9 to 16 inches long and from 1-6th to 1-4th of a line broad, in pools of fresh water among the rocks of the seashore of Point Judith, R. I. One specimen (*Mermis crassicaudata*, Pr. A. N. S., v, 263), opaque white and 8 inches long, I found in a ditch below Philadelphia. A specimen (*Mermis ferruginea*, Pr. A. N. S., v, 275), from Brazil, contained in the collection of the Academy, is brown in color and measures 14 $\frac{1}{2}$ inches long. A cream-colored individual, 4 inches long and 1-5th of a line broad, was obtained from an apple by Major Le Conte, who, with great probability, supposed it had issued from the larva of a lepidopterous insect in the core of the fruit. Professor Agassiz sent me a specimen, translucent yellowish white in color and 9 $\frac{1}{2}$ inches long and 1-5th of a line wide, obtained from the abdomen of *Orchelium gracile*, Harris. Lastly, I have obtained specimens very frequently from *Locusta carolina* of the meadows below Philadelphia, and occasionally from the earth and ditches in the same locality. From one to six of the worms occupy the body of a single insect, closely coiled among the viscera, from the head to the end of the abdomen. The worms are opaque white and measure from 3 to 15 inches in length and from 1-6th to 1-4th of a line in breadth. When the grasshoppers infested with these parasites are bruised the worms creep out and penetrate into the earth, as I have satisfied myself by careful observation. In alcohol the *Mermis* of the grasshopper assumes in time a bright yellow hue.

172. *Mermis Robusta*, Leidy.

Filaria lycosæ, Haldeman. Iconog. Encyc., ii, Zoöl., 48. Body cylindrical, robust, rigid, smooth, and shining, attenuated towards the extremities; most narrowed anteriorly. Head conical, caudal extremity obtuse, imperforate.

I found one specimen, of a pale pinkish white, 3 inches in length and 1-4th of a line in breadth, which crept from the abdomen of a species of *Lycosa*, with four stripes on the cephalothorax and three on the abdomen, from New Jersey. The specimen described by Mr. Haldeman was pale reddish and over five inches in length by 2-5ths of a line in breadth, and was obtained from *Lycosa scutulata*? Hentz, in Pennsylvania.

[September, 1856. No. 164. See Bibliography.]

Dr. Leidy also directed the attention of the members to several shells of the oyster and clam (*Ostrea virginiana* and *Venus mercenaria*) much perforated, which are common on the ocean shore, where they are noticed by all visitors. Dr. L. had for a long time suspected that the perforations were due to some molluscos animal or a worm, and he had frequently sought for them. The last summer, in dredging, in company with Mr. Ashmead and Prof. Baird, on an old oyster bed at Great Egg Harbor, New Jersey, a large number of these perforated shells were obtained, and all of them were observed to be occupied by a sulphur yellow sponge of the genus *Cliona*. This boring sponge forms an extensive system of galleries between the outer and inner layers of the shells, and protrudes through the perforations of the latter tubular processes, from one to two lines long and one-half to three-fourths of a line wide. The tubes are of two kinds, the most numerous being cylindrical and expanded at the orifice in a corolla form, with their margin thin, translucent, entire, veined with more opaque lines, and with the throat bristling with silicious spiculae. The second kind of tubes are comparatively few, about as one to thirty of the other, and are shorter, wider, not expanded at the orifice, and the throat unobstructed with spiculae. Some of the second variety of tubes are constituted of a confluent pair, the throat of which bifurcates at the bottom. Both kinds of the tubes are slightly contractile, and under irritation may gradually assume the appearance of superficial wart-like eminences within the perforations of the shell occupied by the sponge. Water obtains access to the interior of the latter through the more numerous tubes, and is expelled in quite active currents from the wider tubes.

In structure the sponge is composed of an intertexture of granular matter and pin-like silicious spiculae. Several species of *Cliona* are indicated by European naturalists, but are not characterized with sufficient detail to determine whether the one above indicated is distinct or not from them.

Dr. L. further adds, it might appear only of scientific interest to observe a structure so low as the sponge is classified in the organic kingdom, endowed with the power of penetrating such dense and hard bodies as the shell of the clam and oyster, but he suspected that the agency of the boring sponge was a highly important one in the sequence of natural phenomena, as it is a means by which dead shells are rapidly decomposed to be dissolved in the ocean water, where they may again serve as the elements of construction of the habitations of the rising generations of molluscous animals. In confirmation of this view Dr. L. stated that an extensive bed of oysters, which had been planted by Mr. Thomas Beasley, at Great Egg Harbor, and which was in excellent condition three years since, had been subsequently destroyed by an accumulation of mud. The shells of the dead oysters, which were of large size and in great number, in the course of two years have been so completely riddled by the boring *Cliona* that they may be crushed with the utmost ease, whereas without the agency of this sponge the dead shells might have remained in their soft muddy bed, devoid of sand and pebbles, undecomposed perhaps even for a century.

[February, 1857. No. 178. See Bibliography.]

Dr. Leidy made the following observations on entozoa found in the *Naiades*.

He had observed a curious parasite allied to *Aspidogaster conchicola*, infesting *Anodonta fluviatilis* and *Anodonta lacustris*, within the cleft of the upper branchial cavity, adhering to the outer surface of the renal organ and the contiguous margin of the foot. The new parasite, for which the name of *Cotylaspis insignis* was proposed, is from $\frac{1}{2}$ a line to 1 line long, curved funnel-shaped, with the base forming an oval ventral disk provided with an outer circle and an inner row of acetabula 29 in number. The animal is provided with distinct eyes, while *Aspidogaster*, in accordance with its being imprisoned in the pericardium of the *Naiades*, is blind.

[December, 1857. No. 183. See Bibliography.]

Dr. Leidy called the attention of the members to a bottle containing numerous specimens of a large species of *Gordius* discovered by

Dr. Wm. A. Hammond, 525 miles west of Fort Riley, Kansas Territory. Dr. Hammond states they were found in a pond in great numbers, in company with *Siredon*. They swam actively forward an inch or two beneath the surface of the water, and occasionally lifted the anterior end even above the latter.

The collection contains 24 females and the same number of males. The females are cylindrical, light brown of various shades, shining, iridescent; anterior extremely narrowed; head surrounded with a dark-brown ring; tail obtuse, slightly compressed, with a terminal genital pore. The males are darker colored than the females; tail extremity more or less spirally enrolled, with the extremity bifurcated; forks divergent, incurved, smooth, connected at base anteriorly by a crescentic fold, in advance of which is the genital pore; head as in the female.

The females measure from 10 inches in length by 1-3d of a line thick, to two feet 6 inches in length and 3-5ths of a line thick: the males 8 inches in length by 1-4th of a line thick, to 2 feet 2 inches in length by 2-5ths of a line thick.

Dr. Leidy next directed the attention of the members to a bottle containing seven specimens of the larva of a species of *Oestrus* or bot-fly. They were obtained by Dr. Hammond from a pouched rat, *Thomomys borealis*, at Bridger's Pass, on the summit of the Rocky mountains, July, 1857. Dr. Hammond found the rat panting on the road side, without power of escaping. The bots were found situated beneath the skin of the back, belly, and thigh.

The body of these larvæ is oblong oval, compressed, incurved: head minute, composed of a transverse pair of papillary eminences, each supporting two minute ocelli, and having projecting from beneath, forward and downward, a pair of strong black hooks. Spiracular laminæ trilobed and marked with vermicular lines. Segments of the body closely covered with discoidal corneous tubercles, of which the anterior ones have their posterior border projecting and dentated.

The smallest is light yellowish brown, and as they become larger they assume a darker tint. The largest are black, hard, shining, and remarkably shagreened in appearance.

Length of the smallest larva 5 lines, breadth 3 lines, thickness $2\frac{1}{2}$ lines; length of largest 9 lines, breadth $5\frac{1}{2}$ lines, thickness 3 lines.

[**April, 1858. No. 197. See Bibliography.]**

Dr. Leidy called the attention of the members to a drawing of a curious worm, which he said was obtained from the Schuylkill

river, and was interesting from its being more nearly allied to marine forms than any other known fresh-water species. It lives in tubes of mud, and is about a line in length. The body is divided into twelve annuli, including the head, which is cup-shaped; has two eyes, and supports on each side a process provided with seventeen cylindrical ciliated arms. The rings, except the head, are provided with four rows of bristles and two rows of podal hooks. The bristles are from four to six in a bunch, those anteriorly having a falcate extremity and those posteriorly being whip-like. The anterior hooks are in a series of five, and have a long handle with a lance-like extremity. The posterior hooks are from fifteen to twenty in a series, and have a long handle with the extremity expanded and serrated on one side. It appears to be most nearly allied to the marine genus *Fabricia*. He proposed for it the name *Manayunkia speciosa*, from the Indian name of the river in which it was first discovered.

[April, 1858. No. 198. See Bibliography.]

CONTRIBUTIONS TO HELMINTHOLOGY.

Cotylaspis, Leidy. Body curved infundibuliform, anteriorly cylindro-conical, posteriorly expanding into a subcircular or oval ventral disk, with numerous acetabula arranged in a triple series. Mouth infero-terminal, with a prominent upper lip, and protractile into a cup- or disk-like acetabulum. Intestinal apparatus as in *Aspidogaster*. Eyes two, distinct, black, situated on each side of the head. Generative apertures inferior, between the head and the ventral disk.

Cotylaspis insignis, Leidy. Proc. Nat. Sc., 1857, 18.

Translucent white or pink white. Upper lip snout-like, conical. Ventral disk crenate at the margin; acetabula 29, oblong quadrate, the outer rows continuous in front and behind so as to form a circle. Length from $\frac{1}{2}$ to 1 line; ventral disk from 1-4th to $\frac{1}{2}$ a line in diameter.

Habitation.—Found adhering to the outer surface of the renal organ and the upper margin of the foot, within the cleft of the upper branchial cavity of *Anodonta fluviatilis* and *A. lacustris*.

Remarks.—This curious parasite, though allied to *Aspidogaster couchicola*, is certainly distinct; and it never occupies the locality of the latter, which also is found in the pericardium of *Anodonta fluviatilis* and *A. lacustris*. It is an interesting fact that in accord-

ance with its exterior position *Cotylaspis* possesses well-developed eyes, while the imprisoned *Aspidogaster* is blind. It has occurred to me that perhaps these two genera may represent two different stages of existence of the same animal.

Rhopalocerca Tardigrada, Diesing. Attached to the mantle of *Anodonta fluviatilis*; specimens also obtained by Mr. Lea from *A. lacustris*.

Heterostomum Echinatum, Filippi. From the oviduct of *Paludina decisa*. Quite common.

Cercaria Agilis, Leidy. Body, when elongated, narrowed pyriform; when shortened, obovate; posteriorly emarginate; anteriorly triangular. Mouth acetabuliform, large, globular. Acetabulum little larger than the mouth, nearly central in the shortened condition of the body, at the posterior third of the latter when elongated. Sporocerca as long as the body, long clavate, transversely plicated. Color white.

Exceedingly active; found in the Delaware river, quite commonly in company with *Planorbis*, *Paludina*, and *Lymnaea*.

Diplostomum Grande, Diesing. Head oblong oval, a little oblique: margin entire, inflated. Mouth small, round. Male aperture small round, female aperture large prominent, longitudinally oval. Body conical. Ovaries dusky yellowish. Length 1 line; breadth 1-4th line; head 3-4ths line long; body 1-4th line long.

Twenty specimens were obtained from the intestines of *Strix nivæa*.

Monostomum Affine, Leidy. Body spatulate, narrowest anteriorly, flat: posterior end obtuse with an excretory orifice communicating with a well marked canal traceable as far forward as the commencement of the oviduct. Mouth round, oral acetabulum small, followed by a smaller pharyngeal bulb. Intestine simple, traceable on each side to the posterior end of the body. Testes four, posterior to the position of the distended oviducts. Ovaries finely lobulated, situated on each side external to the position of the intestine; oviduct transversely tortuous and distended with brown ova. Penis ensheathed, long, tortuous, echinate. Generative aperture small, acetabuliform. Ova oval and prolonged at one pole, or subopyriform. Length of body $6\frac{1}{2}$ lines; breadth 1 line.

Four specimens were obtained by Dr. J. M. Corse from the bile ducts and gall-bladder of the muskrat (*Fiber zibethicus*). Closely allied to *M. hippocrepis*, Diesing, but has no trace of the horseshoe-like collar to the head.

Monostomum Spatulatum, Leidy. Body flat, oblong, ovate, narrowing anteriorly, obtuse posteriorly; color white, with brown tortuous lines indicating the course of the oviduct. Mouth acetabuliform, circular. Testes three, alternating on each side, posteriorly with the oviduct. Ovaries on each side finely lobulated. Generative aperture small, a short distance behind the mouth. Penis undistinguishable. Length 3 to 4 lines; breadth $\frac{1}{2}$ line.

Twenty-three specimens were obtained by Prof. Jeffries Wyman from the gall-bladder of a fish, the species of which has been forgotten.

Distomum Biliosum, Leidy. Body ovoid, anteriorly compressed, conical, and incurved, posteriorly robust and obtuse. Mouth sub-terminal, transversely semicircular or crescentic, acetabulum much larger than the mouth, sessile subcircular, with a large transversely elliptical and bi-polar aperture. Generative aperture a little in advance and to the left of the acetabulum and provided with a prominent circular lip. Length from 1 to $2\frac{1}{2}$ lines; breadth 1-3d to 1 line; thickness 1-4th to 3-4ths of a line.

Several hundred specimens were obtained from the gall-bladder of a fish by Prof. Wyman, but the species has likewise been forgotten.

Tetrabothrium Barbatum, Leidy. Body delicate, filiform, quadrilateral, anteriorly narrowing, and then slightly widening again towards the head, posteriorly three or four times the breadth of the thickness; anterior segments quadrate, with the posterior angles projecting into barb-like lobe; posterior segments transversely oblong quadrate, with the posterior margin on each side projecting into a festoon-like lobe. Neck none, or a mere constriction. Head larger than the commencement of the body, conical. Bothria four, oblique, marginal, subcircular, large, fornicate, and folded at the border. Mouth at the summit of a globular papilla, unarmed. Length from 1 to 5 inches; breadth anteriorly 1-5th line, posteriorly 2-3ds of line.

Numerous individuals were obtained from the intestine of a large *Odontaspis punctata?* caught on the coast of New Jersey.

Dibothrium Speciosum, Leidy. Head gradually narrowing to its extremity, which is funnel-shaped and truncated. Bothria two, long, marginal, as wide as the head. Neck none. Anterior articuli short, subcuneate, those succeeding transversely sub-reniform, those posterior more equally quadrate, with convex margins, except the back one, which is emarginate. Length $1\frac{1}{2}$ inches; breadth ante-

riorly 1-10th line, posteriorly 2-5th line. Head $\frac{1}{2}$ line long, 1-10th line wide. Generative aperture lateral.

Obtained by Mr. Noah Kollar from the intestine of *Boleosoma olmstedii*.

Acanthorhynchus Reptans, Diesing. Obtained from the drum-fish, *Pogonias chromis*. Smallest individuals, from 1-4th to 1 inch long by $\frac{1}{2}$ line broad, were contained in cysts, adhering to the intestines, in the peritoneal cavity. One 3 inches long, with the head 2 lines long, was found in the liver. The largest ones were coiled up in oval masses, imbedded among the muscles of the tail. Two masses measured each about three inches long by 10 lines in diameter. The worm was several feet in length by $1\frac{1}{2}$ to 2 lines thick, white and soft. Head oval $\frac{1}{2}$ inch long by 1-4th wide. Tail end obtuse.

Filaria Solitaria, Leidy. Syn. of Entozoa, Pr. A. N. S., viii, 56.

Agamoneema Papilligerum? Diesing, Leidy. Ibid., 55.

Filaria Quadriflora, Leidy. Ibid., 56. In error, described posteriorly foremost.

Filaria nitida, Leidy. Ibid., 56. Probably the young. Body cylindrical, slightly narrowed towards the extremities, rose-red in color. Head sub-acute; mouth with two series of four or six minute, conical pointed papillæ. Caudal extremity obtuse; anus terminal, transverse, elliptical, bordered by a prominent lip. Length up to 6 inches; breadth to $\frac{1}{2}$ a line.

A not unfrequent position for this worm, of full size, is beneath the skin of the back of *Rana pipiens*. Found also in the peritoneum and abdominal muscles of *Chelonura serpentina*, not unfrequently in the muscles of the eel, *Muraena macrocephala*, of the Delaware river. In the peritoneum of *Emys serrata* and *Esox reticulatus*.

Oesophagus Tortuosa; white, one-sixth the length of the body; intestine straight or slightly tortuous, translucent.

This parasite is most frequently found during the winter and spring. It is generally bright rose-red in color, with the extremities tinged more deeply red.

Filaria Spirocauda, Leidy. Body long, filiform, most narrowed posteriorly, head obtuse, unarmed; mouth a minute circular pore, neither armed nor labiated. Tail short, conical, rather obtuse, subacute; anus just above the tail. Caudal extremity of female recurved; of male, wound into a spiral of three or four turns. Length of female 6 to 8 inches; breadth $1\frac{1}{3}$ d of a line. Length of male 4 inches; breadth $1\frac{1}{5}$ th of a line. Seven females and four males

were obtained by Professor Wyman from the heart of a seal, *Phoca vitulina*.

Filaria Insignis, Leidy. Body cylindrical, narrowed posteriorly. Head obtuse; mouth quadrate ovoidal with a brownish papilla above and below it, and two almost obsolete ones on each side. Caudal extremity abruptly attenuated into an unciform tail. Length 1 foot; breadth 3-4ths of a line.

A single specimen was obtained by Professor Wyman from a cyst beneath the integument of the foot of a Raccoon, *Procyon lotor*.

Prosthecosacter Inflexus, Diesing.

Prosthecosacter Minor, Diesing.

A large number were obtained from the bronchia and lungs of *Delphinus phocaena* by Professor Wyman.

Gordius Varinus, Leidy. Trans. Amer. Philos. Soc., vol. x, Pl. II, fig. 48. An embryo of this species from *Lumbriculus limosus*.

Ascaris Spiculigera, Rud. Body narrowed anteriorly, inflexed; head naked; tail short, conical, acute. Mouth with large prominent lips. Caudal extremity of the male furnished with a row of minute tubercles on each side. Length of female 8 to 16 lines; breadth to 3-4ths line; length of male 5 to 8 lines; breadth 1-3d line.

From the stomach of *Pelicanus americanus*; Mr. S. Ashmead, Florida. The crested cormorant (*Carbo dilophus*): obtained by Mr. Robert Kennicott, Illinois.

Ascaris Depressa, Rud. From the intestine of *Strix nivea*.

Spironoura Gracile, Leidy. From the Axolotl (*Sirendon mexicanus*).

[**June, 1858. No. 199. See Bibliography.**]

Dr. Leidy, by permission of the Academy, communicated the fact that about one-half of the chrysalides of the canker-worm (*Endalimia*), which had recently proved so destructive to the foliage of our shade trees, were infected by two species of Ichneumon. One of the latter is comparatively large: and a single individual occupies the body of a canker-worm chrysalis. The other species is minute, and numerous individuals occupy the interior of a chrysalis.

[**May, 1858. No. 212. See Bibliography.**]

Dr. Leidy exhibited a drawing of the *Echinococcus hominis*, commonly known under the name of hydatid. The specimen from which it was taken was found in a tumor seated in the muscles of the right iliac region, which had been supposed to consist of impacted faeces in the colon. The patient had been dead several days when the body

was injected with chloride of zinc ; yet two days afterwards the parasites were still alive. None of the injection, however, had come into contact with it, as it had no direct communication with the body. The *Echinococcus* is the larval form of a tape-worm. Dr. Leidy described its mode of propagation and of locating itself in the body.

[May, 1858. No. 213. See Bibliography.]

Dr. Leidy exhibited a minnow, caught in the Schuylkill, having disease of the scales of the upper part of the head and about the orbit. The scales were dilated, and filled with delicate organic cells much resembling carcinomatous cells. They were certainly not confervoid or fungous, but were purely pathological, and thus of interest as a specimen of diseased formation in a fish. Disease in the inferior animals, and even in plants, is deserving of study by medical men, since it may throw light upon the nature of disease in man.

[December, 1858. No. 216. See Bibliography.]

Dr. Leidy called the attention of the members to the stomach of a mink (*Mustela vison*), containing a large number of worms. The latter had caused much thickening of the walls of the stomach, in which the anterior extremity of their body deeply penetrated. The worm is a species, heretofore unnoticed, of the genus *Cheiracanthus*. Its name and characters were given as follows :

Cheiracanthus Socialis, Leidy. Body cylindrical, posteriorly obtuse, anus subterminal. Integument transparent, with distinct circular muscles. Head discrete, discoidal, furnished with transverse rows of recurved hooks. Mouth bilabiate ; œsophagus clavate, red ; intestine dusky brown. Ovaries and oviducts, or testes and vasa deferentia, very tortuous and white. Anterior portion of the body thickly covered with alternating transverse rows of minute plates, of which those most anterior are tridentate, the succeeding ones bidentate, and the last ones are simple and gradually become obsolete. Posterior extremity of the male attenuated, spirally contorted, and ending in a horseshoe-like border with four red papillæ on each side.

Length of female 15 lines ; breadth 3-4ths of a line ; length of male 12 lines, breadth $\frac{1}{2}$ a line.

[December, 1858. No. 217. See Bibliography.]

Dr. Leidy exhibited specimens of true bone found in the kidney of a mink. It was situated in the fibrous tissue of the organ, the glandular substance of which was wasted away, its place being occupied by an enormous parasite, the *Strongylus gigas*.

[January, 1859. No. 219. See Bibliography.]

Dr. Leidy exhibited a drawing of the worm described by him at a former meeting as *Manayunkia speciosa*.

Dr. Leidy remarked that perhaps some of the members present would recollect he had some time since (Proc. 1858, p. 90) described a curious fresh-water worm, *Manayunkia speciosa*, from the River Schuylkill. It was observed that it appeared to be most nearly allied to the marine genus *Fabricia*. During the last summer Dr. L. in company with Mr. Powell sought for the latter at Newport, R. I. They found it in very great abundance at the foot of the cliffs bathed by the ocean. In its curved tubes of tenacious mud, adhering to stones and with its projecting tentacles, it very much resembles a ciliated polyp, especially *Plumatella*.

The worm is about $1\frac{1}{2}$ lines long, demi-cylindroid, with 12 annuli, of which all except the first are setigerous. The cephalic annulus has a short proboscis, is provided with one or two pairs of eyes, and supports 6 arms with about 80 ciliated tentacles. The succeeding 7 or 8 annuli are provided on each side with fascicles of from 5 to 7 setæ and as many podal spines. The posterior 3 annuli are provided on each side with fascicles of 2 setæ and from 12 to 15 short podal spines. Anterior setæ terminating in a linear lanceolate blade; posterior setæ aristate. Anterior spines terminating in a hook, which is dentate on its convex border; posterior spines expanded at the extremity, which is dentate on the convex border. Caudal annulus with a pair of eyes.

Eyes exist in the cephalic and caudal annuli, also in the young worm. From the want of a good description and figures of the European species of *Fabricia*, it was not to be determined whether the American species was different from it.

[February, 1859. No. 232. See Bibliography.]

Dr. Leidy exhibited specimens of a *Trichina* found in the muscles of a human subject. He stated that he often meets with this parasite, and most frequently in the biceps muscle of the fore-arm: also specimens of a dipterous larva from man.

[March 1860. No. 238. See Bibliography.]

Dr. Leidy called the attention of the members to a specimen of the singular body called *Hyalonema mirabilis*, recently presented by Dr. Ruschenberger. It is the second specimen obtained within a short time for the Academy. Both are from Japan. The specimen of *Hyalonema* exhibited consists of a twisted cord of siliceous spiculae over a foot in length and about half an inch in diameter. Twisted around it is a coriaceous membrane with wart-like eminences, belonging to a zoöphyte, which Dr. L. regards with M. Valenciennes as parasitic. The cord of siliceous spiculae Dr. J. E. Gray supposes to be the axis of the zoöphyte, but Dr. L. with M. Valenciennes views it as belonging to a sponge. This latter view is apparently confirmed by a specimen of a sponge, in the cabinet of the Academy, from Santa Cruz, presented by the late Dr. Griffith. This sponge is an oblong oval mass, about four inches long, surmounted at one extremity with a corona of twisted cords of siliceous spiculae about two inches in length. These spiculae are very similar in structure to those of the *Hyalonema*, mainly differing in size.

[April 1860. No. 239. See Bibliography.]

Dr. Leidy stated that he had just received a short notice from Prof. Leuckart, of Giessen, in which he mentions the results of some experiments with *Trichina spiralis*. Having fed dogs with human flesh containing Trichinæ, he found that in a week or less the worms completed their development, but without assuming the form of a *Tricoccephalus* or *Strongylus*. Within the intestine of the dog the generative apparatus, together with the eggs and embryos, were fully developed in the Trichinæ. The embryos rapidly passed away with the excrement of the dog. A pig, having been feed with a dog's intestine containing fully developed Trichinæ, was killed and dissected on the 3d of March, and exhibited in the muscles millions of Trichinæ. From these facts it is rendered probable that embryos of Trichinæ voided by dogs find their way into the human stomach through the food or drink, and subsequently burrow into the tissues of the body.

[March 1866. No. 271. See Bibliography.]

Dr. Leidy next directed the attention of the members to a specimen of the liver of a turkey suspended in alcohol, containing half a dozen cream-colored tumors, from the size of a pea to that of a nutmeg. The tumors examined microscopically appear to have the

structure of *soft cancer*, as usually described, being composed of large nucleated cells in great variety of form. Dr. L. stated that, after having dined on part of the turkey, on making inquiry for the missing liver, the cook had given information that in consequence of the "white lumps in it, it had not been cooked." On procuring it from the slops, it was found to be in the condition described. Dr. L. took the opportunity of expressing the opinion that an unnecessary degree of alarm had been created in the community in relation to what were considered to be diseased meats, especially such as are infested with parasites. While he most decidedly recommended the avoidance of the flesh of diseased or unwholesome animals, he thought that all parasites would be destroyed by thorough cooking.

In answer to a question from one of the members, whether he had noticed Trichina in pork, Dr. L. observed that he had been the first to discover this parasite in the hog, the discovery having been made twenty years ago, as may be seen by referring to the Proceedings of this Academy for October, 1846, pages 107, 108. This notice had attracted the attention of the German helminthologists, as proved by reference to Diesing's *Systema Helminthum*, vol. ii, page 114, and Leuckart, *Untersuchungen v. Trichina spiralis*, pages 6, 18.

[March, 1866.]

The circumstances under which the Trichina had been first detected in pork were on an occasion when Dr. L. had dined on part of the infested meat. While eating a slice of pork he noticed some minute specks, which recalled to mind the Trichina spots seen in the muscles of a human subject only a few days previously. Preserving the remainder of the slice, on examination of it microscopically he found it full of *Trichina spiralis*, but the parasites were all dead from the heat of cooking. In conclusion, Dr. L. observed that all meats were liable to be infested with parasites, but that there was no danger from infection if the meats were thoroughly cooked, for he had satisfied himself by experiment that entozoa are destroyed when submitted to the temperature of boiling water.

[October, 1868. No. 297. See Bibliography.]

NOTICE OF SOME AMERICAN LEECHES.

Having been invited by Mr. R. H. Lamborn, secretary and treasurer of the Mississippi and Lake Superior Railroad Company, to join an excursion to Minnesota and Lake Superior the last summer,

during the trip I had the opportunity of making many interesting observations in natural history. The many lakes of Minnesota are rich in mollusca, annelides, &c. Among the annelides, besides an abundance of the ordinary American medicinal leech *Hirudo decora*, I noticed one which struck me from its general resemblance to a variety of the European medicinal leech, *H. medicinalis*. One of the gentlemen in company with us, Mr. Clark, allowed me to try upon him its disposition to bite, but I did not succeed in getting the animal to do so. Upon examination of the leech, I find it belongs to a different genus from *Hirudo*, apparently to the genus *Aulastomum*. Its characters are as follows:

Aulastomum Lacustris, n. s. Body cylindroid, compressed, narrowing anteriorly, obtuse at the sides (in movement more cylindroid or less flattened, and quite obtuse laterally compared with *Hirudo decora* in the same condition). Color throughout olive green (with more of a yellowish hue than in the dorsal green of *H. decora*), closely maculated everywhere with confluent spots of a darker hue of the same color. Ninety-two annuli, exclusive of the lips, of uniform width, smooth. Upper lip half ovate, obtuse; lower lip narrow. Eyes ten, eight in the upper lip, the last pair separated by an annulus from the others. Mouth obliquely terminal, large. Acetabulum subbasilar, ventral, sessile, circular. Anus dorsal, above the acetabulum. Male aperture in the 24th annulus (but apparently between the 23d and 24th). Female aperture in the 29th annulus (apparently between the 28th and 29th). Oesophagus capacious, extending to about the 22d annulus, with 12 folds. Jaws three, small, when at rest included in pouches formed by an eversion of the mucous membrane. Teeth 12 in number to each jaw, bilobed at base. Length 4 to 5 inches, breadth 5 lines posteriorly; acetabulum 2 lines in diameter.

Var. An individual of lighter olive green than the former had black maculae replacing the darker green ones, which were also more distinct and fewer.

Specimens described from Twin Lake, Minnesota.—In the summer of 1865 I saw several leeches at Sault Ste. Marie, in Lake Superior, which, so far as I can remember, were of the same species. At the edge of the shore I also saw some cocoons which I supposed to belong to the same animal. They were ochreous yellow, oval, about 4 or 5 lines in diameter; the surface impressed with concave pentagonal and hexagonal pits. From the angles of the margins of the latter projected branching processes curling at the ends.

Notwithstanding our familiarity with the American medicinal

leech, its long and frequent employment in the medical profession, and the vast numbers which have been brought to notice, it has been so imperfectly described that, in the excellent *Systema Helmintium* of my late esteemed friend, Dr. Diesing, of Vienna, it has been placed with the "Bdellidea species genere penitus dubiae." I therefore take the present opportunity of indicating its characters more fully. It agrees most nearly with the diagnosis of the genus *Hirudo*, of which the *H. medicinalis* is the type, but nevertheless possesses peculiarities perhaps rather more than specific. Its characters, generic and specific, are as follows:

Hirudo Decora. Say: Long's Expedit., vol. ii, 1842, Append., 268. Moquin Tandon: Monog. Hirud., 1846, 344. Diesing: Syst. Helm., i, 1850, 474. Wood and Bache: United States Dispensatory.

Body elongated, compressed cylindroid, narrowing anteriorly, laterally sub-acute; in motion convex above, flat below, with the margins compressed, thin, acute, and somewhat wavy; composed of from 90 to 94 annuli, which are uniform and smooth. Head continuous with the body. Mouth obliquely terminal, bilabiate; the upper lip prominent, semiovate, obtuse, or from contraction of the lip emarginate; lower lip forming the inferior portion of the first annulus: the lips together acting as an acetabulum ovoid or obcordate in form. Eyes 10, arranged in horseshoe form, the anterior 8 above the upper lip, the posterior pair separated from the others by the first annulus. Acetabulum subbasilar, ventral, sessile, circular. Anus dorsal, above the acetabulum. Male aperture perforating the 25th annulus, with the lips more or less prominent. Female aperture between the 29th and 30th annuli. A group of four papillæ situated back of the latter on the 34th to the 36th annuli inclusive. Jaws three, semicircular, laterally compressed, furnished with 55 teeth, which have an acute curved summit and an expanded bilobed base. Oesophagus short and narrow compared with that of *Aulastomum*, furnished with 6 longitudinal folds, of which three coarse ones descend from the jaws and three narrow ones are intermediate.

Color.—Dorsal surface olive green, with a median irregular band and a lateral line of darker hue of the same kind: a median row of reddish brown dots, and a lateral row of black dots. Ventral surface reddish brown, extending slightly above the lateral margin, devoid of spots, or more or less maculated with black. Acetabulum colored like the back above and the belly below.

In the genus *Hirudo*, as characterized by Diesing (Syst. Helm., i, 465), and to which he assigns 9 recognized species, the jaws are furnished with from 60 to 70 teeth, and the male aperture is situated

between the 24th and 25th segments. Moquin Tandon (Monog. Hirud., 1846, 326) likewise assigns the latter as the position of the male aperture in the genus *Hirudo*.

The position of the generative apertures in *H. decora* often appear more or less discolored or of a dull purplish hue, and the same is the case with the group of papillæ back of them. The latter do not exist in the medicinal leech of Europe. They are quite conspicuous in ours. I have suspected that they were provided for the adherence of individuals in sexual intercourse, and this view is confirmed by Mr. S. J. Moore, the well known professional leecher and bleeder of this city. Mr. Moore informs me that in copulo two individuals adhere in the position of the papillæ and make two turns of a spiral upon each other.

The red and black spots of the back contain from 20 to 22 in each row.

Length up to 7 inches by 8 lines in breadth posteriorly, and the acetabulum 3 lines in diameter.

[October, 1868.]

Prof. Leidy directed attention to a specimen of a sponge which had been for many years in the Museum of the Academy and had been presented by the late Dr. R. E. Griffith, who obtained it in the Island of Santa Cruz, W. I. It is especially interesting from its relationship with that most beautiful of all known sponges, the *Euplectella aspergillum*, and apparently also to that enigmatic body, the *Hyalonema Sieboldii* of Japan. Specimens of both these were also exhibited: a beautiful one of the former, from the Philippines, presented to the Academy by Joseph Henry Craven. Several specimens of the *Hyalonema*, presented by Drs. Ruschenberger and Sinclair, consist of a twisted fasciculus or rope of long, coarse, translucent siliceous threads, partially twisted with a brown verrucose membrane or bark. When the first specimen was presented to the Academy, in 1860 (Pr. A. N. S., 1860, 85), Prof. Leidy, as curator, reported it as a part of a sponge with a parasitic polyp upon it. One of the specimens may have some significance as to the relation of the rope of spicules and its polyp covering. It has attached two shark eggs and part of the tendril-like cords of another. The tendrils clasp the rope, and are also partly invested with the polyp crust. In the complete condition the *Hyalonema fasciculus* appears always to be associated at one end with a sponge mass. Originally described by Dr. R. E. Gray, the fasciculus was viewed as the axis of a coral, of which the verrucose bark formed part, the warts

constituting the polyps; and he supposed the fasciculus to grow as a parasite from the sponge, frequently seen in specimens attached to one of its extremities. This still appears to be the view of Dr. Gray as announced in recent volumes of the Proceedings of the Zoölogical Society, etc.

Dr. Bowerbank views the siliceous rope, with its warty investment and the sponge mass at one end, altogether as the elements of a sponge. The warts or polyps of Dr. Gray he regards as the oscules of the sponge.

Schultze, in an elaborate memoir (*Die Hyalonemien*), accompanied by beautiful plates representing the complete *Hyalonema*, as the result of his investigations determines the sponge mass and projecting siliceous rope to be altogether the elements of the sponge, and the warty investment of the rope to belong to a polyp, to which he gives the name of *Polythoa fatua*. In the crusts or individual polyps he detected the arms filled with nettling cells.

Brandt views the siliceous rope and its investment as a polyp, and the sponge mass at one extremity as a parasite invading, ultimately to destroy the polyp.

Lastly, among the discordant views, Ehrenberg looks upon the siliceous rope as an "artificial product of Japanese industry."

Prof. L. continued, I shall not discuss this extraordinary difference of opinion among experts, but must confess that I view most favorably the theory that the sponge mass and the siliceous rope together constitute the sponge *Hyalonema*, while the warty crust of the rope constitutes a parasitic compound polyp, the *Polythoa fatua* of Schultze.

The sponge from Santa Cruz, in its body and projecting fasciculi of siliceous threads, reminds one of the *Hyalonema* sponge, with its siliceous rope, but the structure of the threads of the former more nearly resembles those of the anchor threads of *Euplectella*. It is evidently a different sponge from either of those just named, and may be called *Pheronema*.

The body of the sponge is oblong ovoidal, with the narrower end upward, and with one side more prominent than the other. The lower extremity is rather cylindroid and rounded truncate. The upper extremity is conical, with a truncate apex presenting a large circular orifice. This is about 4 lines in diameter, and is the exit of a canal which descends in the axis of the sponge for almost half its depth, and then appears to divide into several branches. The sides of the sponge form thick dense walls to the cylindrical canal, which is of uniform diameter before its division.

In its present condition the sponge is of a light-brown hue. Its surface exhibits an intricate interlacement of stellate, siliceous spiculae, including a tissue of finer spiculae of the same character, the whole associated by the dried remains of the softer sponge tissues. More or less fine sand, especially at the lower end of the sponge, appears to be introduced as an element of structure.

From the lower end of the sponge there projects a number of distinct or separate tufts of siliceous spiculae, looking like tufts of blonde human hair. In the specimens there are 15 tufts projecting around two-thirds of the extremity of the sponge, but the remaining third of the extremity of the latter exhibits about 10 orifices, from which as many additional tufts appear to have been extracted.

Length of the body of the sponge $4\frac{1}{4}$ inches; diameter at middle 22 lines, at lower end 15 and 17 lines, at upper end 8 lines. Length of tufts of spiculae 2 inches. The coarser stellate spicules of the surface of the sponge in general have 5 rays, of which 4 are irregularly cruciform, while the fifth projects at a right angle to the others towards the interior of the sponge. The rays of the continuous crosses form together a lattice work on the surface of the sponge, and the intervals are covered by the rays of the finer spiculae, which also in general have a five-rayed stellate character. The finer tissue in the interior of the sponge, seen through the lattice work of the surface, contains a multitude of spicules which differ from the others only in their minute forms. Some of the largest stellate spicules on the surface of the sponge have a stretch of three-fourths of an inch.

The spicules of the tufts projecting from the sponge are two or three inches in length and vary in diameter. They become attenuated towards both extremities, but especially that inserted into the sponge mass. Starting from the latter, they are at first smooth, then finely tuberculate, the tubercles gradually become converted into well marked recurved prickles or hooks, and finally the spicules end in a pair of longer hooks, recalling to mind the arms of an anchor. The spicules bear a near resemblance to those at the lower extremity of *Euplectella*, but have only two instead of four hooks at the end. In the specimen but few of the spicules present the complete character as described, most of them apparently having been broken.

The object of the tufts of spicules, with their recurved prickles and anchor-like free extremities, in *Pheronema* would appear to be to maintain the position or preserve the anchorage of the sponge in its ocean home, and perhaps in the living animal they are incessantly

produced as occasion may require, just as a *Mytilus* or a *Pinna* renews and attaches its threads of byssus to secure its position.

The siliceous spicules of *Phoronema* are composed, as in sponges generally, of concentric layers, and exhibit a delicate tubular axis. A spicula from one of the tufts measured as follows:

Spread of the anchor 1-10th of a line; shank of the anchor 1-30th of a line; prickled portion of shaft 1-40th of a line; shaft where thickest and without prickles 1-18th of a line, thinning out to the inserted end where it was not more than 1-300th of a line.

The species I propose to dedicate to my wife under the name of *Phoronema annae*.

[September, 1870. Nos. 317 and 335. See Bibliography.]

Prof. Leidy stated that during the last summer he had made some further observations on *Urnatella*, a genus of ciliated polyps of the family Pedicelliniidæ, discovered by him some years ago (Pr. Ac. Nat. Sc., 1851, 321 : 1854, 191) in the Schuylkill river. It is found abundantly below the dam at Fairmount, adhering to stones and rocks, on the sides and under part, not in contact with the ground. Occasionally it is observed attached to the shell of the living *Unio complanatus* and *Melania virginica* and less frequently to the stem of *Schollera graminea* and the leaves of *Vallisneria spiralis*. In the locality named, on the rocks, there may be observed, in association with *Urnatella*, the following animals: *Spongilla fragilis*; *Limnias ceratophylli*, usually abundant and in compound bunches; *Cothurnia pusilla*, parasitic on *Urnatella* and *Limnias*; *Hydra carnea*, Ag.; *Paludicella elongata*, *Plumatella vesicularis*, and the worm *Manayunkia speciosa*, etc.

[June, 1870. No. 326. See Bibliography.]

Prof. Leidy next made some remarks on the family of the Vinegar-eels, the substance of which was as follows: The number of species and genera of nematoid worms represented by the Vinegar-eels and constituting the family Anguillulidæ is astonishingly great. They are found in multitudes frequently in and about moist decaying and fermenting organic substances. Mr. Bastian, of London, a few years since contributed to the 25th volume of the Transactions of the Linnean Society a paper, in which he has given descriptions, with characteristic figures, of most of the known species, including about one hundred new ones, which he observes he discovered from a few limited regions in England in the course of fifteen months.

In seeking for the source of the small thread-worm, or *Oxyuris vermicularis*, which infests man, I have also been led to discover some new species, of which I propose in due time to publish descriptions with drawings. As is commonly the case in organic nature, we find the specific form changing with the change in condition, but the species are often found to differ where differences in the conditions are hardly appreciable.

Mr. Bastian, in a note to his description of the Vinegar-eel, *Anguillula aceti*, says he was indebted to Dr. Davaine for the opportunity of examining the animals, and adds that "they are much less frequent than is generally imagined—at all events in England: and this may be due in great measure to the adulteration of our vinegar with sulphuric acid." It would thus appear that the *Anguillula aceti* he examined was contained in a specimen of what may be suspected to have been the wine vinegar of France. The cider vinegar so commonly used in this country usually teems with vinegar eels. Our vinegar cruetts, when held up to the light, even to the sharp sight of a naked eye, frequently exhibit the worms swarming, especially at the border of the surface, as if in search of both air and light. By comparison of our cider Vinegar-eel with Mr. Bastian's description and drawings of the true *Anguillula aceti*, which I infer to be the wine Vinegar-eel, it appears to belong to a different species. From the descriptions of previous authors of the European Vinegar-eel, I had considered ours as the same. I shall not now give a description of the animal, proposing to do so in the future, together with other species. I may say, however, while it has nearly the size and form of the *Anguillula aceti*, it has the œsophagus of the form in the genus *Cephalobus* of Bastian.

[August, 1870. No. 331. See Bibliography.]

Prof. Leidy exhibited in a vessel of water numerous living specimens of a leech, which he said was abundant in the vicinity of Philadelphia, but appears to be an undescribed species. He had first observed it in a pond on the Delaware, near Beverly, Burlington county, N. J., from which he obtained the largest specimens. It was found especially beneath half-submerged dead limbs of trees, sometimes between the bark and the wood, and in crevices and holes of the latter made by insects. It was also found in the Delaware and Schuylkill rivers near shore, beneath stones. In ditches below the city, and communicating with the rivers mentioned, smaller leeches, apparently the young of the same, were frequently between the leave sheaths of submerged stems of aquatic plants,

such as *Zizania aquatica*, *Scirpus fluviatilis*, *Sagittaria*, *Sparganium*, &c. When disturbed the animal receded from its position of rest and swam rapidly like the ordinary medicinal leech, *Hirudo decora*. It appears to belong to a different genus from the latter, and approaches most in character *Nephelis*, though it even exhibits points of difference from this as ordinarily described. The more mature animal from the Beverly pond may thus be characterized:

Body elongated, flattened cylindroid, narrowing anteriorly, smooth, indistinctly annulated, margin acute, above blackish olivaceous, below translucent grayish, with a more or less reddish tinge due to the blood. No striae or markings visible beneath, and the annuli in this position scarcely perceptible. Annuli about 98, above minutely punctated with yellowish olivaceous or dusky whitish, and narrowly defined by the same hue. Head continuous with the body, obtuse. Mouth large, obliquely terminal, sub-bilabiate; lower lip crenulate. Jaws three rudimental folds without teeth. Oesophagus capacious, with three longitudinal folds. Intestine simple. Anus dorsal, conspicuous, in the penultimate annulus. Eyes six; anterior pair largest and approximated; second pair in second annulus corresponding with the lower lip; third pair smallest, more deeply situated than the others, and placed slightly external and posterior to the second pair. Acetabulum terminal, inferior, circular, nearly as wide as the body. The larger male aperture conspicuous, and situated about one-fifth of the length of the body from the head; the smaller female aperture scarcely visible and situated two or three annuli back of the former. Length to $2\frac{1}{2}$ inches by two lines wide; by contraction becoming shorter and wider.

Smaller specimens, from half an inch to an inch in length, from the ditches communicating with the Delaware and Schuylkill rivers, and from the latter agree in form and constitution with the preceding, having the same number of annuli to the body and the same number and disposition of the eyes. The color is translucent pale Indian red, passing into darker shades and without the colored punctæ. Some young pale individuals exhibit a few scattered minute black punctæ down the back, due to single pigment cells, but mostly these are absent. Intermediate sized individuals from the Delaware and Schuylkill exhibit a gradation of character between the two forms indicated. Further numerous young from the ditches, kept in an aquarium for the last month, have gradually assumed the appearance of the more mature animal as first described.

Nephelis vulgaris of Europe has eight eyes, and the generative apertures are included between the 34th and 38th annuli. In the species above described I could detect but six eyes, and the annuli at the fore part of the body are too indistinctly defined to determine the exact relative position of the generative apertures.

The new species of *Nephelis* I would propose to name *N. punctata*.

[March, 1871. No. 347. See Bibliography.]

Prof. Leidy made the following remarks on *Tenia medicocancellata*: Recently one of our ablest and most respected practitioners of medicine submitted to my examination a tapeworm which had been discharged from a young man after the use of the aspidium filix-mass. The physician, in giving an account of the case, stated that he had previously treated the patient for another affection, in which raw-beef sandwiches had been prescribed for food. After looking at the worm, I remarked that it appeared to be the *Tenia medicocancellata*, a species which I had not before seen, and added that the patient had probably become infected from a larva swallowed with the raw-beef sandwiches. The specimen consisted of the greater part of the worm, broken into several pieces. Including some lost portions, it was estimated to have been upward of thirty feet in length. Unfortunately, the head proved to be absent; but, so far as character could be obtained from the specimen, in the form of the segments, position of the genital orifices, and the condition of the ovaries, it agreed with the description given of *T. medicocancellata* rather than with *T. solium*. From a want of acquaintance with the former, I did not feel entirely satisfied that the specimen actually belonged to that species.

Subsequently my friend brought to me the anterior part of the body, probably of the same individual tapeworm. He observed that, his patient continuing to complain, he had administered another dose of the male-fern, which was followed by the expulsion of the portion of the worm now presented. The head of the parasite was included, and it confirmed the view that it pertained to the *Tenia medicocancellata*.

The case serves as another caution against the use of raw flesh as food.

The description of the worm, as derived from the specimen, is as follows:

The head is white, without pigment-granules, obtusely rounded, unarmed with hooks, and unprovided with a rostellum, but furnished with a minute acetabuliform fovea at the summit. The four ace-

tabula are spherical, and opaque white. The diameter of the head is three-fourths of a line. The neck, or unsegmented portion of the body immediately succeeding the head, is about 4 lines long by half a line in breadth. The most anterior indistinctly defined segments of the body, and those immediately succeeding them, but more distinctly separated, are about one-fifth of a line long by two-fifths of a line broad. In a more posterior fragment of the body the flat and nearly square segments measure half a line long and a line broad to one-third line long and $2\frac{1}{2}$ lines broad. A succeeding fragment exhibits segments $3\frac{1}{2}$ lines long by 4 lines broad, and 2 lines long by 5 lines broad. Many of the segments in this piece are irregularly separated, laterally, by deep, wide notches. In a succeeding long portion of the worm the segments are wider behind than in front, and measure 2, 5, and 3 lines long by 5 lines broad. In a long piece of the posterior part of the worm the segments are first 4 lines long and broad, and in the last four feet of the same piece the segments are clavate in outline, from 6 to 10 lines long, and 2 and 3 lines broad.

The genital apertures are conspicuous, and are situated behind the middle of the segments. They alternate irregularly. Thus, in the last two feet of the posterior fragment of the worm, the first two segments exhibit the aperture on the left margin: the succeeding segment presents the anomaly of an aperture on both margins, then follow three apertures on the right, next two on the left, then four on the right, then eight alternating in pairs, then one on the left, and so on. The ovaries are opaque white, and exhibit numerous closely crowded lateral branches.

In the absence of pigment-granules to the head, and in the less robust character of the worm, the specimen differs from *T. mediocanellata* as described by Kuchenmeister. The minute acetabular pit or fovea at the summit of the head is not mentioned by Kuchenmeister and subsequent observers as a character of that species. It is a point, however, that might be readily overlooked, especially if parts of the head are obscured by the presence of pigment-granules. (Drawing.)

[November, 1871. No. 361. See Bibliography.]

FLIES AS A MEANS OF COMMUNICATING CONTAGIOUS DISEASES.

Prof. Leidy remarked that at this time, during the prevalence of smallpox, he was reminded of an opinion he had entertained that flies were probably a means of communicating contagious diseases to a greater degree than was generally suspected. From what he had

observed in one of the large military hospitals, in which hospital gangrene had existed, during the late rebellion, he thought flies should be carefully excluded from wounds. Recently he noticed some flies greedily sipping the diffluent matter of some fungi of the *Phallus impudicus*. He caught several, and found that on holding them by the wings they would exude two or three drops of liquid from the proboscis, which, examined by the microscope, were found to swarm with the spores of the fungus. The stomach was likewise filled with the same liquid, swarming with spores.

[December, 1871. No. 362. See Bibliography.]

Notice of Some Worms.—Prof. Leidy remarked that Prof. Hayden reports the brook trout, *Salmo fontinalis*, of the headwaters of the Yellowstone River, to be much infested with a species of tapeworm. A number of specimens of the worm, collected by C. Carrington, have been submitted to his examination, but, unfortunately, most of them are so far decomposed as nearly to be reduced to the condition of pulp. The worms are stated to have been taken from the abdominal cavity, but not from the intestinal canal, and often were found beneath the skin, extended among the muscles or inclosed in oval sacs. Several cysts preserved entire contained worms in a better condition for examination than the others, and from these the characters of the parasite have been ascertained. It belongs to the old genus *Bothrioccephalus*, and to that section now named *Dibothrium*. Two species of this genus have long been known as infecting the salmon and other members of the same genus of fishes in Europe, but the parasite of the Yellowstone trout appears to be a different one.

Two of the best preserved specimens measured five inches long by a line wide at the broadest part. The head, about a fourth of a line in diameter, is obcordate. The two suckers or bothria are thick and discoidal, placed back to back, obcordate in outline, directed with their broad and slightly depressed surface towards the margins of the body. The body is flat, thick, with rounded margins, and is narrowly annulated or segmented. The annulations, due to muscular bands, measure about ten to a line. Segments, independent of the annulations, if existing, could not be distinguished, perhaps on account of the badly preserved condition of the specimens. No genital apertures are visible at the sides nor at the margins. No internal organs are visible, but the soft, solid interior tissue is filled with round corpuscles resembling starch granules. These are, however,

composed of carbonate of lime, as they are dissolved by acetic acid with an abundant evolution of carbonic acid.

From the form of the head the worm was named *Dibothrium cordiceps*.

Numerous leeches collected by Prof. Hayden's assistants, Messrs. Carrington and Dawes, in a lake in Wyoming Territory, appear to belong to the species *Aulastomum lacustris*, first discovered several years ago in Twin Lake, Minnesota (Proc. Acad. Nat. Sci., 1868, p. 229). Mr. Carrington informs us that the head of a horse, which was thrown into the lake, in a few hours appeared black from the quantity of these leeches which adhered to it. It is barely probable that this leech is the one described by Thomas Say, in Long's Expeditions, under the name of *Hirudo marmorata*, though the characters do not accord with his description of the latter. It is not improbable that the two are quite distinct. *H. marmorata*, together with another species, *H. lateralis*, was obtained from small lakes on the high land between Lake Superior and Rainy Lake. Neither of these appears to have been obtained since their first discovery.

Several large hair worms from Fish Creek, Montana, pertain to the species *Gordius lacustris*, previously described from specimens obtained in Kansas. It is the largest known *Gordius*. The females of the Kansas specimens range from 10 inches to $2\frac{1}{2}$ feet in length, the males from 8 inches to upwards of 2 feet. The females of the Montana specimens measure from $1\frac{1}{4}$ to $2\frac{1}{4}$ feet in length, a male $8\frac{1}{2}$ inches in length. The females are pale brown, the males dark brown and with a strongly forked tail.

[January, 1872. No. 365. See Bibliography.]

On a Mite in the Ear of the Ox.—Prof. Leidy remarked that he had received a letter from Dr. Charles S. Turnbull, in which he stated that while studying the anatomy of the ear he had discovered in several heads of steers, at the bottom of the external auditory meatus, a number of small living parasites. They were found attached to the surface of the membrana tympani. Specimens of the parasite preserved in glycerine, and a petrosal bone, to which several of the parasites were clinging, were also sent for examination. These proved to be a mite or acarus, apparently of the genus *Gamasus*. The body is ovoid, translucent white, about 3-5ths of a line long and 2-5ths of a line wide. The limbs, jaws, and their appendages are brown and bristled. The body is smooth or devoid of bristles. The limbs are from 2-5ths to $\frac{1}{2}$ a line long. The feet are terminated

by a five-lobed disk and a pair of claws, as represented in figure 3. The palpi are six-jointed, as represented in figure 1. The mandibles end in pincers or chelæ, resembling lobster claws, as represented in figure 2. The movable joint of the chelæ has two teeth at the end. The opposed extremity of the fixed joint of the chelæ is narrow, and ends in a hook. (Drawing.)

Whether this mite is a true parasite of the ear of the living ox, or whether it obtained access to the position in which it was after the death of the ox in the slaughter-house, has not yet been determined. Dr. Turnbull observed it only in the position indicated.

[**June, 1872. No 365. See Bibliography.]**

Note on Gamasus of the Ox.—Prof. Leidy read an extract from a letter from Dr. C. S. Turnbull, in which it was stated that the writer had been misunderstood in relation to the acarus of the ox, described in the Proceedings for January 2d. He had seen the cattle killed, and was positive that the mites occupied the position in the ear of the steers while these were alive. Such being the case, the acarus may be viewed as a parasite of the ox, and may be specifically named *Gamasus auris*.

[**April, 1873. No. 389. See Bibliography.]**

Fungus Parasite on a Mouse.—Prof. Leidy exhibited a mouse with several whitish masses adherent to the ears, side of the face, and nose. The mouse had been caught in the children's department of Blockley Hospital, and was submitted to his examination by one of the attending physicians, Dr. James B. Walker, who had informed him that he had observed a number of mice in the same condition. Dr. Walker had previously informed him of the curious affection of the mice, and it was at his suggestion that the present specimen was caught for examination. The white matter, examined beneath the microscope, proved to be composed of sporular bodies, single, double, or in short chains of a dozen or more. They measure about the 1-650th of a line in diameter. The fungus is a *Torula* or *Oidium*, and resembles that found in *Aphtha*. Perhaps the disease in the mice is the result of feeding upon articles imbued with adherent portions of aphous matter from the mouths of children, and perhaps also the latter may become affected from diseased mice contaminating food or drink used by the children.

[October, 1873. No. 390. See Bibliography.]

On Distoma Hepaticum.—Prof. Leidy stated that he had received a letter from Prof. Gross, inclosing one from Dr. J. G. Kerr, of Canton, China, asking information in regard to a worm accompanying the letter. Dr. Kerr observes that the worm was vomited by a Chinese boy, aged fifteen years, and was brought to him in an hour after its expulsion, when it was still alive. It had the appearance of a leech, was red in color, about an inch and a half long and three-fourths of an inch where widest. Dr. Kerr also states that a girl, of four years, of English parents, living in Canton, passed from the bowels at one time nine of these worms. With these exceptions, Dr. Kerr had not met with any one who had ever seen or heard of anything of the kind.

Prof. Leidy exhibited the specimen and expressed the opinion that the worm was a Liver-fluke, *Distoma hepaticum*, a rare parasite in the human subject, though common enough in cattle, especially sheep, in which it caused the disease called "rot." The worm exhibits some differences from *D. hepaticum* as usually described, but perhaps not sufficient to characterize it as a distinct species. The specimen is preserved in strong alcohol, which no doubt has much contracted and reduced it in size, but it is yet rather larger than the size assigned to *D. hepaticum*. It is perfectly smooth throughout, and exhibits no trace of roughness to the integument. It is ovate-lanceolate in form, and gradually widens from the anterior to the posterior rounded extremity. The ventral acetabulum is twice the size of the mouth, and is situated about its own diameter behind it. The genital orifice with the exserted spiral penis is placed just in advance of the ventral acetabulum. The measurements of the worm in its present condition are as follows: Length 17 lines, width at the posterior third 7 lines, thickness near center 1 line, diameter of mouth 2-5ths of a line, diameter of acetabulum 4-5ths of a line.

Prof. Leidy further remarked that Dr. Keyser, of this city, the evening previously had brought to him for examination a worm, which was stated to have been removed from the cavity of the nose of a patient. He recognized the worm as a rat-tail lava (*Larva?*) apparently of the genus *Eristalis*, and inquired of those members interested in entomology, if they had ever known this insect to be found as a parasite in the human body. Both Drs. Le Conte and Horn said that they had never heard of this genus being parasitic.

[August, 1874. No. 405. See Bibliography.]

On a Parasitic Worm of the House-fly.—Prof. Leidy remarked that since it had become well known that many parasitic worms passed different stages of development within several different animals, he had from time to time sought for the sources from whence the more common thread worms obtained entrance into the human body, but thus far without success. The *Trichina spiralis*, discovered in man in 1833 by Mr. Hilton, and described and named by Prof. Owen in 1835, was first found in the hog by Prof. Leidy in 1846 (see Proc. A. N. S., iii, 108), but it was not until some years subsequently that it was determined that man and the hog acted reciprocally as hosts for the *Trichina* in its different stages of development.

In examining various common animals of our household, Prof. Leidy had found a thread-worm infesting the common house-fly. The worm is from a line to the tenth of an inch long, and lives in the proboscis of the fly. It was found in numbers from one to three in about one fly in five. The parasite was first discovered in the house-fly in India by the English naturalist, Mr. H. J. Carter, who described it under the name of *Filaria Muscae*, and suggested the opinion that it might be the source of the Guinea worm, *Filaria medinensis*, in man. Mr. Carter states that he found from two to twenty of the worms in one fly of three. Dr. Diesing referred the parasite to a new genus with the name of *Habronema muscae*. The singular position in which the worm lives suggests the many unsuspected places we have to search to find the parents or offspring of our own parasites.

[January, 1875. No. 416. See Bibliography.]

On a Fungus in a Flamingo—Prof. Leidy remarked that a pair of Flamingoes had recently died in the Garden of the Zoölogical Society at Fairmount Park. Dr. Chapman, who had dissected the birds, called his attention to the diseased condition of the lungs of one of them, the other not being affected in this respect. The posterior part of the lungs on both sides, contiguous to the abdominal air sacs, was occupied by an indurated brown substance, in striking contrast with the usual bright roseate hue of the neighboring pulmonary tissue. An incision made into the indurated substance exhibited a brown compact surface with greenish-black dots which corresponded with the bronchial tubes. On microscopical examination the substance was found to be pervaded with a fungous vegetation, and the greenish-black dots were due to the fruit heads profusely covered with colored spores.

Prof. Owen, upwards of forty years ago, mentioned the existence of a green mould he had observed in the lungs of a Flamingo, which died in the menagerie of the Zoölogical Society of London, but he gave no description of the plant by which we can recognize it. Since then many accounts have been given of the existence of fungous vegetation in the diseased lungs of various birds, but I think it has not been determined whether the diseased condition was due to the fungus or whether this was a subsequent production.

The plant observed in our diseased Flamingo belongs to the Moulds or Mucedines, and is evidently an *Aspergillus*. A number of species of this genus have been described, growing on various decaying substances. The common Blue Mould found in cheese and bread kept in a damp place is the *Aspergillus glaucus*. From this the mould of the Flamingo is quite distinct in the structure of the fruiting receptacles, in which respect it more nearly resembles the *Aspergillus dubius*, growing on rabbit's dung. The *Aspergillus* of the Flamingo I suspect to be the same as one described by M. Robin under the name of *Aspergillus nigrescens*, discovered by him in the lungs of a pheasant (*Pheasianus colchicus*) affected with phthisis.

In the Flamingo mould the mycelium consisted of a dense flock of delicate ramifying filaments pervading the indurated pulmonary tissue, which consisted largely of nucleated cell elements and granules. The threads of the mycelium were branching, and occupied on the interior with clear globules appearing like rows of beads. The threads measured usually the 1-500th of a millimeter or less in diameter.

The fruiting stems (see accompanying figure) were straight, from one-fourth to two-fifths of a millimeter long, not articulated, usually simple, and rarely divided, approximating a right angle near the head. They were about the 1-250th mm. wide at the mycelial origin and double the width approaching the head. The head continuous with the stem was pyriform, or the stem expanded into a globular receptacle, which was closely crowded with linear processes or sporophores, supporting the spherical, translucent colored spores. The latter profusely invested the heads, but were too ripe and readily detached to determine their exact arrangement in relation with the sporophores. These, on the contrary, remained firmly attached to the receptacle.

The receptacles measured from 1-60th mm. to 1-50th mm. The stratum of sporophores was from 1-166th mm. to 1-125th mm. thick. The spores were 1-333d mm. in diameter.

By transmitted light the spores appeared so faintly colored that the tint was undetermined; by reflected light in mass they appeared of a greenish hue. The receptacles, including the sporophores, appeared fuscous by transmitted light, but white by reflected light.

In M. Robin's plate of *A. nigrescens* he represents most of the fruiting stems as articulated, but in our plant none of this character were detected.

[February, 1875. No. 417. See Bibliography.]

Notes on Some Parasitic Worms (with drawing).—Prof. Leidy remarked that Mr. Henry Horn, assistant superintendent at the Zoölogical Garden, had given to him several specimens of worms, recently passed by a Bengal tiger. There are three males and eight females, and they appear to be the *Ascaris mystax*, which has been found in many other feline species, including the domestic cat and the lion. The characters of the worms from the tiger are as follows: Body almost equally tapering towards the extremities. Female—Cephalic end inflexed, with long narrow semi-lanceolate alæ. Caudal end straight; tail short, conical, subacute. Male—Cephalic end straight, alated. Caudal end inflexed, and furnished with a row of about two dozen minute round papillæ on each side ventrally; tail short, conical, acuminate. Length of females from 2 to $3\frac{1}{4}$ inches; thickness from 1-4th to $\frac{1}{2}$ line. Length of males from 13 to 16 lines; thickness from 1-6th to 1-5th line.

Prof. Leidy further remarked that Mr. Thomas Mecham had submitted to his examination some worms which had been found in an apple. They consisted of one entire individual and the anterior half of a second, and apparently pertain to the *Mermis acuminata*, a long thread-worm which has been discovered infesting the larvae of many insects. Among others, it is parasitic in the larva of the codling-moth, or fruit-moth of the apple, which readily accounts for its presence in the fruit. Twenty-five years ago (Proc., 1850, 117) he described a worm, belonging to the collection of the Academy, and labeled as having been obtained from a child's mouth, which was evidently the same species. It having been in the child's mouth is probably to be explained by supposing that the child had eaten an infected apple.

The characters of the present specimens of the worm, both females, are as follows: Body filiform, pale fuscous, narrower anteriorly. Head conical, truncate, with the mouth simple and unarmed. Caudal extremity thicker than the head, obtusely rounded, and furnished with a minute spur-like process. Length 5 inches 8 lines;

cephalic end at mouth 1-12th mm.; a short distance below 1-5th mm.; middle of body 3-8ths mm.; near caudal end 1-4th mm.; mucro 1-12th mm. long, 1-80th mm. thick.

From an Australian wombat, which recently died at the Zoölogical Garden, Prof. Leidy had obtained from the stomach two specimens of a tapeworm of the genus *Tænia*. They are three inches long, and about four lines broad at the last joint. The characters are as follows: Entire worm elongated and compressed pyramidal. Head quadrate, narrowing below, convex above, furnished laterally with four prominent hemispherical bothria. Neck short, constricted. Segments of the body very short and wide, campanulate with the projecting points, giving the body laterally a serrated appearance. From the intermediate joints a narrow conical papilla protruded from each side of the same joint, but none could be made to protrude from the back joints, from which globular white ova were expressed measuring 0.052 mm. diameter. Head 3-4ths of a line in breadth. One inch from the head six segments occupied the space of a line; at the posterior part of the body four segments occupied the same extent. The species appears not to have been previously described, and may therefore be named *Tænia bipapillosa*.

[February, 1875. No. 418. See Bibliography.]

Notes on Some Parasitic Worms.—Dr. Leidy exhibited some nematoid worms, on which he made the following remarks:

One of the species is common in feline animals and is the *Ascaris mystax*. The specimens, consisting of fifteen females and five males, had been sent to Dr. Chapman by Mr. Thompson, superintendent of the Zoölogical Garden, who reports that they had been passed by the American wild-cat. The females measure from $2\frac{1}{2}$ to 4 inches in length by 2-5ths to 2-3ds of a line in thickness. The males measure from $2\frac{1}{4}$ to $2\frac{1}{2}$ inches in length by 1-3d to $\frac{1}{2}$ a line in thickness. The specimens are larger and the ale of the head proportionally better developed and therefore more conspicuous than in those noticed at the previous meeting as having been passed by the Bengal tiger. The worms of the tiger are such as have been described under the name of *Ascaris leptotera*, which appears to be only a variety of *A. mystax*.

The other worm is a *Filaria*, apparently an undescribed species. Half a dozen individuals of the two sexes were obtained from the peritoneal cavity of an Australian Whallabee, which recently died in the garden of the Zoölogical Society. The characters of the parasite are as follows:

Filaria Spelaea.—Body filiform, translucent whitish, tapering at the extremities. Cephalic end straight, obtusely rounded, furnished with four equidistant papillæ around the mouth. Caudal end narrowest, rather abruptly attenuated and spirally rolled once or twice and terminating obtusely. A distinct anal aperture observable in the female. A row of eight papillæ on each side ventrally of the caudal end of the male; three in advance and the others back of the genital aperture. Penis a long, tubular style, thick at the upper part, narrow and curved below. Accessory piece a short, thick, curved tube, widening at the upper end in a spade-like, furcate portion. Oesophagus long, cylindrical, as wide as the succeeding intestine.

Measurements.—Female, length 10 inches, thickness 1-4th line. Length of tail from anal aperture 7-8ths mm. Male, length 4 to 4½ inches; thickness 1-66th inch. Tail, from genital aperture, forms 2-3ds of a circle 1₂ a mm. in diameter. Penis 7-8ths mm. long; accessory piece 1-5th mm. long.

[April, 1875. No. 423. See Bibliography.]

On Psorosperms in a Mallard Duck.—Prof. Leidy remarked that Dr. Elliott Coues had recently submitted to his examination some portions of the flesh of a mallard duck preserved in glycerine. The interstices of the muscles of the duck were stated in the letter which accompanied the specimens to be everywhere occupied by abundance of parasites. Specimens of these in the portions of flesh examined proved to be oval white bodies from one to two inches long and about one-third of a line thick. Beneath the microscope they were found to contain myriads of fusiform corpuscles, resembling minute naviculae and measuring about the 1-1500th of an inch in length. Similar bodies were first discovered in many fish by the late Prof. J. Müller and described by him as parasites under the name of *Psorospermis*. They have been repeatedly observed since by Retzius, Robin, and others in the muscles and other parts of fishes, and they are usually regarded as vegetable parasites. I have not previously heard of similar organisms having been detected in birds. Though the mallard is not a fish-eater, the bird may have become infected by having swallowed an infected fish.

[September, 1875. No. 424. See Bibliography.]

On Mermis Acuminata.—Prof. Leidy exhibited a living specimen of *Mermis acuminata*, which had been sent to him for examination

the 8th of last August by Mr. P. H. Foster, of Babylon, Long Island, N. Y. It was one of two specimens which Mr. Foster had taken from apple worms found concealed in a woolen rag tied around the trunk of an apple tree in his garden. The mermis is $7\frac{1}{2}$ inches long, and had been retained alive in a box with moist sphagnum. It exhibits a condition which Prof. L. had observed on several previous occasions in other species of *Mermis*. An intermediate portion of the body, apparently from injury, had died and was decomposed, while the extremities held together by the integument were still alive and active. This condition has been observed to be maintained for some time—that is to say, for some weeks.

[April, 1877. No. 438. See Bibliography.]

*On Intestinal Parasites of *Termes Flavipes*.*—Prof. Leidy remarked that in seeking small animals beneath stones and fragments of wood in our forests, observing the very common White Ant, *Termes flavipes*, he noticed that the intestine of the insect, seen in the translucent abdomen, was distended with brown matter. Feeling curious to learn the exact nature of this matter, he was surprised to find that it consisted largely of infusorial and other parasites, mingled with minute particles of decayed wood. In many instances the parasites are so numerous as to make up the greater portion of the bulk of the intestinal pulp. Every individual he had examined, of workers, soldiers, and winged forms, was infested with the parasites, which may be estimated by millions. As the discovery to him of this new world of parasitic life was recent, he had not yet had time to sufficiently examine scientific literature to ascertain whether the parasites had been discovered and described by others. M. C. Lespes, in a memoir on the organization of the *Termes lucifugus* of France, published in the *Annales des Sciences Naturelles* for 1856, remarks that the intestine is usually occupied by a kind of brown pulp, a living agglomeration of infusoria, and in another paper in the same volume, after describing a nematoid worm, *Isacis migrans*, infesting the *Termes*, he remarks that he had found in the intestine of the insect a great quantity of parasites, upon which he proposed to say something in the future.

The parasites observed in our White Ant consist of five different kinds, of which three are animal and two vegetable in character. One of the latter consists of filaments of the alloid form he had once described under the name of *Arthromitus*: the other, not so frequent, is a *Spirillum*, probably *S. undula*.

The animal parasites, of which drawings were exhibited, are as follows:

1. *Trichonympha Agilis*. This is a remarkable creature of obscure affinity, but probably related with the *Turbellaria* on the one hand and by evolution with the *Ciliate infusoria* on the other. The animal is about 1-300th of an inch long and about half the breadth of the length. It is fusiform, and is clothed with ciliate hairs of extraordinary length. The head is mammilliform; the posterior end of the body from subacute to obtuse according as it is narrowed or shortened by contraction. The cilia investing the body appear to consist of three sets—the shortest ones waving outwardly and downward from the head; a second set extending from the head the length of the body, incessantly waving downward and swelling outwardly, and the third set, the longest of all, extending from the head beneath the others in a longitudinal spiral manner far beyond the posterior end of the body, where they form a loosely twisted fascicle with divergent ends. The arrangement of the long cilia clothing the body reminded him of the nymphs in a recent spectacular drama, in which they appeared with their nakedness barely concealed by long cords suspended from the shoulders, and this arrangement has suggested the name applied to the parasite.

He was not positive whether he had been able correctly to interpret the interior structure of the animal, but it appeared to him to resemble more that of the *Rhabdocoela* than that of any of the protozoa. No appearance of vascular or nervous system could be detected. The animal appeared to be capable of ingesting particles of solid food, frequently observed in considerable quantity in the stomach occupying the posterior two-thirds of the body. The mouth apparently was a rounded pore at the summit of the head. From this a narrow tube expanded in a pharyngeal pouch communicating behind with the capacious stomach. An anal outlet may exist at the back end of the body, but was not detected. Opposite the conjunction of the pharyngeal pouch and the stomach a granular nuclear body is constantly observed.

Trichonympha, though incessantly and actively in motion, usually remains stationary in position, but occasionally advances with feeble jerking propulsion. The chief movements consist in frequent retraction or shortening and bending of the cephalic end with rapid waving and swelling outwardly of the long ciliary hairs. The motion of the latter resembles the flowing of a thin sheet of water over the brim of a fountain vase or basin swayed to one side or the other by a current of wind. The longest cilia, extending beyond the back

of the body in a loosely twisted fascicle, are the least active, but at times stretch outwardly and become more divergent at the ends, or they become more closely applied to the sides of the body. When the head is bent to one or the other side, with the summit directed forward, it gives rise to an appearance resembling the spiral peristome of a *Stentor*. Viewed on end, the parasite appears circular with long divergent cilia, and reminds one of the upper view of a *Vorticella*.

2. *Pyrsonympha Vertens*. The two remaining animal parasites are Infusoria. The larger of the two is often more abundant than the *Trichonympha*, and is about the 1-200th of an inch in length. It is more delicate, less distinctly defined, and undergoes rapid dissolution after removal from the intestine of the Termite. It is elongated fusiform, or, when shortened, clavate or pyriform in outline. Like *Trichonympha*, it usually remains stationary in position, while actively moving, writhing, apparently twisting, and often bending in a waving manner from one extremity to the other. In motion, longitudinally spiral and parallel lines become more or less evident and frequently cause serrated projections at the extremities or at the prominence of the bends when produced at the lateral borders. These exhibit a rapid waving motion, strikingly resembling the movement of flames and probably denoting the presence of minute cilia, though these were not positively seen. A narrow band extends the length of the body, sometimes projecting at one end, and moves in long angular waves, flexing the body in accordance with its movement. The body appears to be composed of finely granular protoplasm, with but faint distinction of endo and ectosare. A large oval or round granular nucleus occupies a position in advance of the middle of the body. The position of the mouth was not detected, though one is most probably present, as the animalcule is often replete with large particles of food, consisting of bits of wood. *Pyrsonympha* may be the larval condition of *Trichonympha*, though there is no evidence that such is the case.

3. *Dinenympha Gracilis*. A Ciliate Infusorian, the smallest and most abundant of the three animal parasites, about 1-350th of an inch in length, is flattened, fusiform, and in motion often twisted. It is longitudinally and, in the twisted condition, spirally striated, and is invested everywhere with fine cilia. The animal usually, remaining like its companions nearly stationary in position, writhes from side to side, shortens and widens, or lengthens and contracts, and rotates in the long axis. The longitudinal lines of the body by contraction produce a serrated appearance at one end, or at the

prominences of the lateral borders when the body is twisted. The interior of the body is finely granular, often with one or more large globules, probably consisting of a nucleus, and at times of contractile vesicles or vacuoles. No mouth could be detected, although one probably exists, as the animal often contains particles of solid food, sometimes comparatively of enormous size.

The great accumulation of parasites, apparently constantly existing in the White Ant, one of our most common insects, will afford a new and wonderful source of delight to our microscopists. They should be examined in a denser liquid than water, as this produces their rapid destruction. The white of an egg thinned with water Prof. L. finds to be a good medium in which to examine these and other minute parasites from the interior of animals.

The nematoid worm *Isacis migrans*, discovered by M. Lespes, so abundantly existing within the *Termes lucifugus*, and also externally in the nest of this insect, in France, Prof. L. has occasionally found in the *Termes flavipes*.

[**May, 1877. No. 439. See Bibliography.]**

Remarks on Gregarines.—Prof. Leidy remarked that his recent study of the Rhizopods had led him once more to make an examination of some of the Gregarines, regarded as pertaining to a nearly related class.

The Gregarines are especially parasites of the Articulata, most of the known forms having been found in insects, crustaceans, myriapods, and annelides. Most of those observed by himself were found in vegetable and dirt feeders. They frequently occupy the alimentary canal, but in some animals occupy other organs or the perivisceral cavity. With few exceptions, the Gregarines at maturity consist of a comparatively large nucleated cell, which for convenience may be named the body cell, continuous at one pole with a small non-nucleated cell, which in like manner may be viewed as the head cell. Both cells are filled with fine globular granules, which in mass give the Gregarines a milk-white appearance. No mouth or trace of intestinal organs exists. The outer wall of the cells is a thick, structureless, contractile endosarc, and within this, in the body cell, there is often perceptible, as in *Gregarina larvata* of our common Julius, a well-marked longitudinally striated and apparently muscular layer.

The motions of the Gregarines consist of a kind of peristaltic action of the wall of the body cell proceeding from one to the other end.

In the Gregarines, so common in several species of our earthworms, the head cell is absent, and therefore is very properly viewed as of a different genus from the more ordinary *Gregarina* under the name of *Monocystis*. The *Monocystis agilis* is sausage-like in form, and is usually from 1-3d to 3-4ths of a millimeter in length. In movement its contractions may commence at one end and proceed towards the opposite end, or it may commence at both ends, proceeding towards the middle, or may commence in the latter position and proceed towards the ends.

From the researches of Lieberkühn and others it appears that the Gregarines of earthworms assume a globular form and become encysted, and the granular contents are in a greater measure resolved into navicula-shaped germs, which have been named pseudo-naviculae or navicellæ or psorosperms. Lieberkühn was led to consider the amoeboid perivisceral corpuscles of the earthworm as amoeba-like embryos derived from the navicellæ, but it is very doubtful whether there is any relationship whatever between the two. Both Gregarines and navicella cysts are met with in the intestine of our common earthworm, but the cysts are to be found most frequently and abundantly in the sperm vesicles. In the six vesicles of an earthworm Prof. Leidy had counted 1,540 mature navicella cysts, together with a number of groups of immature cysts. The mature cysts, readily visible to the naked eye as minute pearly-white globules, by transmitted light have a peculiar pale-blue hue. They measure about 1-4th of a millimeter in diameter. A cyst burst open spread its navicellæ over a millimeter square, and was estimated to contain about 2,500. These were quite uniform in size and measured 0.0133 mm. long and 0.00665 broad.

E. Van Beneden has clearly traced the development of the *Gregarina* of the lobster from Amoeba-like embryos, so that it is not improbable that similar embryos may be derived from the navicellæ.

The Gregarines are usually viewed as constituting the lowest class of the Protozoa, and hence the lowest of animals. From their structure and mode of development, Prof. L. considered them as holding a higher rank than Rhizopods, and occupying a position intermediate to these and the Infusoria.

Prof. L. further stated that in a large earthworm, *Lumbricus terrestris*, from the yard of his residence, the posterior pair of sperm vesicles alone contained upwards of a thousand navicella-cysts, besides several thousand Gregarines, *Monocystis agilis*, exhibiting the varieties of condition, such as have been represented by Schmidt, Lieberkühn, and others. Many of the Gregarines were invested with

motionless cilia, while other actively contracting individuals possessed no trace of these appendages. Some of the Gregarines further exhibited transition stages towards transformation into navicellacysts. The latter differed from those previously mentioned in having but a single thin membranous layer for their wall instead of many layers.

Prof. L. added that our earthworms, which appear to be the same as the common European species, likewise appear to be infested with the same variety and kind of parasites. Among the latter he had repeatedly observed the infusorian *Anoplophrya lumbrici*, and also several different nematoids. One of these, which he had found in the sperm vesicles, appeared to be undescribed. It was certainly different from the *Dicelis filaria* found in the same organs by Dujardin. It appears nearly related with *Anguillula*, and may be regarded as such with the name of *A. melancholica*. Its characters are as follows: Body cylindrical, tapering at the ends, distinctly annulated. Head truncated, with the vertex convex, and perforated centrally by the mouth, and defined from the sides by an elevated annulus. Tail conical, and ending in a short, thick conical process. Mouth a minute round pore, unarmed; pharynx a short narrow tube; oesophagus long, cylindroid, widening posteriorly, and rather abruptly narrowed at the anterior extremity; gizzard wider than the oesophagus, cylindrical and rounded at the extremities; intestine straight, intensely black or blackish brown. Length from 3 to 4 millimeters; thickness at middle 0.15 m. Length of oesophagus 0.5 m., of gizzard 0.125 m., thickness 0.075 m., thickness of intestine 0.05 m., length of tail from anal aperture 0.175 m. Color black, with the anterior end white. All females. Sometimes upwards of a dozen found in the sperm vesicles of a single earthworm.

[**May, 1877. No. 440. See Bibliography.]**

On Flukes Infesting Mollusks.—Prof. Leidy remarked that our common fresh-water mollusks, especially the gastropods, were much infested with flukes. These appear to be prevalent during the latter part of the year, and absent during the earlier part. Drawings were exhibited of the sporocysts and cercariae of two species of flukes infesting *Planorbis parvus*.

The species were named and described as follows:

Monostoma (Glenocercaria) Lucania. Sporocyst bright orange-colored, cylindroid in form, with obtusely rounded extremities. Pharynx globular, from which is suspended a long cylindrical

pouch-like stomach, black in hue, extending two-thirds the length of the body. Body cavity distended with cercariae in various stages of development. Cercaria white; with a compressed, ovoid body emarginate behind; tail cylindro-conical, pointed, as long or longer than the body, often constricted so as to appear more or less moniliform. Eyes two, black, with an intermediate black pigment spot looking like a third eye, and a number of smaller pigment spots scattered in the vicinity of the eyes. Acetabulum. Pharynx globular; intestine bipartite. A distinct pore situated ventrally near the root of the tail.

Length of sporocysts from 3-4ths to 1 mm. Length of cercariae $\frac{1}{2}$ mm.

The sporocyst is quite active, elongating and shortening; retracting and projecting the pharynx. It also exhibits strong peristaltic movements, in which the body becomes constricted tightly just back of the pharynx or in any position beyond. The contraction gradually extending backward and dividing the body cavity into two compartments, the cercariae are suddenly slipped through the constriction, one after the other from the posterior to the anterior compartment. The movements of the cercariae, liberated from the sporocyst, consist mainly in elongation and narrowing and shortening with widening of the body. Elongation of the body causes it to exceed the length of the tail. At times the lateral extremities of the posterior emargination of the body are prolonged into short conical appendages.

This fluke occurs abundantly beneath the muscular tegument, among the lobes of the liver, and folds of the intestines of *Planorbis parvus*. Upwards of fifty of the sporocysts distended with cercariae have been removed from a single *Planorbis*.

Distoma (Gymnocephala) Ascidea. Sporocyst white. Head distinct from the body, campanulate, varying in the proportion of length to breadth, according to the degree of contraction. Body cylindroid, with a pair of lateral conical appendages, beyond which it extends as a cylindro-conical tail-like prolongation. Pharynx globular, encircled with six equidistant organs (undetermined in character, probably teeth? or perhaps ganglia). Stomach a flask-like pouch extending but a short distance from the head into the body cavity, and not reaching the middle of the latter, even in its most shortened condition; bright brown in color. Body cavity distended with numerous cercariae; the immature ones occupying the tail-like prolongation. An orifice at the extremity of a blunt conical snout communicates with the body cavity just back of the head.

Cercaria, white, with an obcordate or when elongated a clavate body, and a long, narrow, cylindro-conical pointed tail. Cephalic end triangular, and slightly constricted from the rest of the body; posterior part broadly emarginate. A ventral acetabulum near or posterior to the center of the body, and between it and the root of the tail an oval pore. Eyes none. Pharynx globular; gizzard small; divisions of the intestine extending about two-thirds the length of the body.

Length of sporocysts of different ages, from 1-8th to 1 mm. Length of cercariae 1-4th to 2-5ths mm.

In motion the sporocysts contract the head so that it may be of nearly equal length and breadth, and it may be extended so as to be double the length of the breadth. The body also elongates and shortens in the same manner. Cercariae were observed in several instances escaping from the snout-like projection of the body cavity back of the head. The cercariae in movement elongate excessively, and the body may be extended so as to be almost as narrow as the root of the tail. The ventral disk is often protruded into a conical appendage or expanded into a broad cup. The tail becomes longer, narrower, and more pointed, or shorter, wider, and beaded.

This fluke occupies a similar position in the *Planorbis* as in the former, and has been found in equal numbers, but the two species have not been found associated in the same individual. The distoma form of the ascoid fluke, encysted, was also observed in *Planorbis parvus*, without any traces of the generative organs being obvious.

A free swimming cercariae, identical in character with that of the ascoid fluke, has been observed in water, which contained many individuals of *Planorbis parvus* and *Limnaea elodes*. The free cercaria agrees with the description of *Cercaria minuta*, Nitzsch, found with various fresh-water mollusks of Europe.

Prof. L. further exhibited drawings of a *Distoma*, the *Rhopalocerca tardigrada*, Diesing, from the mantle of *Anodon fluviatilis*; a second, the *Heterostomum echinatum*, Diesing, from the oviduct of *Paludina decis*a, and a third from *Helix aborea*, thus described:

Distoma Appendiculata.—Translucent white, band-like, widest in front and rounded at the head, tapering behind and truncate at the end. Pharynx and ventral disk large and nearly equal and about 1-8th mm. diameter. The gizzard comparatively large and oval. Intestine bifurcate with the branches parallel, and with an intermediate pouch-like appendage extending nearly half way to the position of the ventral disk. A posterior opening communicating

with a pouch and a water vascular system. No traces of a generative apparatus observable. Length 1 mm.

[June, 1877. No. 442. See Bibliography.]

REMARKS ON THE SEVENTEEN-YEAR LOCUST, THE HESSIAN FLY,
AND A CHELIFER.

Prof. Leidy remarked that he had returned last evening from a short visit to Easton. He stated that the Seventeen-year Locust, *Cicada septendecim*, had made its appearance in the vicinity of that town. He further stated that the wheat in the same locality was seriously affected by the Hessian Fly, *Cecidomyia destructor*, which has now passed into the puparium stage. In one field examined half the crop was destroyed by the insect. He further remarked that his little daughter brought to him an Elater, *Alaus oculatus*, and, on her account, professing to attach some interest to a common insect, in examining it with more than usual attention, he was surprised to find concealed beneath the elytra six Chelifers. He was not aware whether the Elater was commonly infested in this manner. In another specimen subsequently found there were no Chelifers. The Book-scorpion, *C. muscorum*, appears not to be common with us, as he rarely met with it. He had occasionally met with another species, perhaps *C. cancrioides*, attached to the House-fly. The Chelifer of the Elater is different from either of those just named, and is perhaps an undescribed species. Its characters are as follows:

Chelifer Alius.—Body in general chestnut brown; the pedipalps and the dorsal shield of the cephalothorax being darkest; the abdomen lightest, and in the largest individuals, probably females, whitish with transverse dorsal and ventral bands of brown. Body with the sides nearly parallel, but widening slightly posteriorly, being widest near the termination of the abdomen, except in the largest female, in which it is widest near the middle of the abdomen. Maxillary palps shorter or not longer than the body; intermediate joints of the same about twice the length of their thickness. Length of body from $1\frac{1}{2}$ to $2\frac{1}{2}$ mm.; length of pedipalps from $1\frac{1}{2}$ to $1\frac{9}{16}$ mm. All parts are hairy, but the abdomen of the largest ones is less so than in the others.

The species bears much resemblance in form and color to the *C. reussii*, Koch. It also resembles the *C. americanus*, De Geer, but it does not possess the knob on the penultimate joint of the pedipalp.

[June, 1877. No. 441. See Bibliography.]

Remarks on some Parasitic Infusoria.—Prof. Leidy remarked that most of the known parasitic infusoria possessed a mouth, as in those which lived free in the waters. Such is the case with the species of *Balantidium* found in the intestinal canal of man, the hog, and various batrachians; of *Nyctotherus*, found in the intestine of frogs, several insects, and myriapods, and the *Conchophthirus anodontae*, often found abundantly in the branchiae and palpi of our *Anodon fluviatilis*.

Other parasitic infusoria are not only devoid of an intestinal canal as characteristic of their class, but have no mouth, and, like the tape-worms and *Echinorhynchus*, absorb nourishment through the exterior surface of the body. Such is the case with the genus *Anoplophrya* of Stein, typified by the *Anoplophrya lumbrica*, found in the intestine of our common earthworms, as well as in those of Europe. Prof. Leidy had also detected the same species in the little wood-worm, *Euchytraeus socialis*, and had found two other species, formerly described by him under the names of *Leucophrys clavata* and *Leucophrys cochleariformis*, in the intestine of *Lumbriculus limosus* and *L. tenuis*.

Recently in dissecting the fresh-water snail, *Paludina decis*a, while examining the branchiae he observed several individuals of an *Anoplophrya* moving actively, as if in antagonism with the ciliary motion of the branchial plates. Seeking the source of the little creatures, he found that they came from the rectum of the *Paludina*. In examining other individuals of this snail he observed that some were free, others were infested with few and some with multitudes of the infusorian. In several instances the *Anoplophrya* were so abundant as to resemble in their crowded condition a mass of writhing worms, actually distending the portion of the intestine they occupied. The species appears to be an undescribed one, and is interesting from its comparatively large size. It was named and described as follows:

Anoplophrya Vermicularis.—Body cylindrical, slightly tapering posteriorly, rounded at the extremities, or subacute behind; flattened at the anterior extremity; translucent white, finely striated longitudinally, uniformly clothed with short cilia; internally finely granular, with a longitudinal cylindrical nucleus occupying nearly the length of the axis, and with from twenty to thirty contractile vesicles, mostly arranged in one, but often in two, longitudinal series. Length from two-fifths to one-half a millimeter; breadth in front, .044 to .048 mm., behind .032 to .04 mm.

Besides the movements of progression induced by the cilia, the animal wriggles in a sigmoid manner and even doubles on itself. The contractile vesicles may contract more or less successively to mere points, but apparently at no time entirely disappear, and they may enlarge to double their usual size. The axial nucleus is at first barely perceptible, but becomes very obvious as the animal approaches dissolution.

Incidentally Prof. Leidy also stated that *Aspidogaster conchicola*, so common in the pericardium of *Anodonta* and *Unio*, he had also found in one instance in the oviduct of *Paludina decisus*.

[September, 1877. No. 444. See Bibliography.]

On the Bed-bug and its Allies.—Prof. Leidy remarked that it was commonly supposed that the swallow, pigeon, and bat were infested with the bed-bug, and that those animals introduced the insect into houses. Packard (Guide to Study of Insects, 551) observes that the bed-bug "lives as a parasite on the domestic birds," and adds that a gentleman informed him "that he has found a nest of swallows on a court-house in Iowa swarming with bed-bugs." Westwood (Introd., ii, 475, note) says it is certain that bed-bugs "swarm in the American timber employed in the construction of new houses." "In the western part of our country," continued Prof. Leidy, "I frequently heard that bed-bugs were to be found at any time beneath the bark of the cotton-wood and the pine. In these positions I never found one, nor have I ever found the insect except in the too familiar proximity of man. Recently, when in the West, while watching some cliff swallows passing in and out of their retort-shaped mud nests built under the eaves of a house, I was told that these nests swarmed with bed-bugs, and that usually people would not allow the birds to build in such places, because they introduced bed-bugs into the houses. Having collected a number of the bugs, as well as others from the interior of the house, specimens of both of which are submitted to the examination of the members, I found that while the latter are true bed-bugs, *Cimex lectularius*, the former are of a different species, the *C. hirundinis*. The bugs infesting the bat and pigeon have likewise been recognized as a peculiar species, with the name of *C. pipistrelli* and *C. columbarius*." Prof. Leidy further noticed that the habit of the *C. hirundinis* was similar to that of *C. lectularius* in the circumstance that the bugs during the daytime would secrete themselves in crevices of the boards away from the nests. After sunset he had observed the bugs leave their hiding places and make their way to the nests. From these obser-

vations it would appear as if the peculiar bugs of the animals mentioned did not reciprocally infest their hosts.

[**March, 1878. No 456. See Bibliography.**]

A Louse of the Pelican.—Prof. Leidy exhibited a portion of the pouch of a pelican, with several groups of large lice adhering to the lining membrane. The specimen, suspended in alcohol, had been presented to him some years since by his late friend, Prof. Jeffries Wyman, who obtained it while in Florida from the white pelican, *Pelecanus trachyrhynchus*.

Later Dr. Elliott Coues, U. S. A., had submitted to his inspection specimens of the same louse, which he had obtained from the interior of the pouch of a white pelican from the Red River of the North.

The Louse pertains to the *Mallophaga*, or Fleece-eaters, and appears to be an undescribed species. The name of *Menopon perale* was given to it. It is $2\frac{1}{4}$ lines in length and of a chestnut-brown color. The head is broader than long, semilunar, with a black spot on each side in advance of the pair of eyes. Prothorax narrower than the head, with a lateral conical point. Abdomen nearly twice the length of the head and thorax together; terminal segment rounded and with a tuft of hairs on each side. Mandibles strong and black.

[**May, 1878. No 457. See Bibliography.**]

On Parasitic Worms in the Shad.—Prof. Leidy stated that during the last month he had received letters and specimens from New York, Trenton, Norfolk, and elsewhere, with information that the shad, this season, was much infested with worms. Two of the writers, physicians, had expressed apprehension in regard to the parasites, and supposed that they had traced several cases of illness to the use of shad which they suspected had been infested with the worms.

The worm has long been known in Europe as a parasite of the herring, mackerel, cod, salmon, and other food fishes. It is the *Filaria capsularia* of Rudolphi, or the *Agamonema capsularia* of Diesing. Prof. L. had described it in the Proceedings of this Academy in 1856, from the shad and herring, and had repeatedly observed it in the same fishes every year since. It usually infests the internal organs, and is often observed encapsulated in a close coil upon the roes, the intestines, and the liver. It is from half an inch to an inch or more long. Most individuals have a few of the parasites, and sometimes they are exceedingly numerous. They appear not to affect the health of the fishes unless they are very numerous, when

they impoverish their hosts. Prof. L. believed that they did not affect the wholesomeness of the fish as food, and perhaps when cooked with the fish were equally good and nutritious. Like others, he felt an antipathy to the worms, and he was in the habit of scraping them off from the roes of smoked herring before eating these. He took the opportunity of adding, what was already well known to naturalists, that most animals are infested with parasites, which were transmitted by feeding on one another. The remedy against transmission was heat. He who uses only well-cooked meats need have no apprehension of worms from such food.

[November, 1878. No. 465. See Bibliography.]

Notices of Gordius in the Cockroach and Leech.—Prof. Leidy exhibited a *Gordius*, which had been submitted to him by Dr. Robert Meade Smith, of this city, with the note that "a servant killed a large cockroach (*Blatta orientalis*?) in the kitchen, and threw it into a tumbler of water, and had then noticed, as she described it, one of its legs growing and swimming off." The *Gordius* is nine inches long, chocolate brown, with darker spots of the same, attenuated anteriorly with the head rounded, and the tail spiral and at the end slightly compressed and roundly truncated. Thickness of the worm anteriorly 1-5th of a line; posteriorly 2-5ths of a line. The species is probably *Gordius aquaticus*.

Prof. Leidy further remarked that twenty years ago he had collected from Lily Pond, R. I., a number of little leeches, of two species of *Clepsine*, which were much infested with delicate hair-worms coiled up in the interior of the body. The Clepsines were the fourth to the third of an inch in length. The most frequent of the species had two eyes; the other had three pairs of eyes. The leeches contained from one to five of the hair-worms, ranging from 10 lines to two inches in length. The worms appear to pertain to a species of *Gordius*, which, from its slender character, may be named *Gordius tenuis*. The worm is white or cream-colored, but has become brown as preserved in alcohol. It is attenuated anteriorly, with the head end tapering and conical. The posterior end is curved, thickened, and obtusely rounded. A short oesophagus is succeeded by a simple, straight, capacious intestine imperforate at the posterior extremity. A worm of two inches in length measured 0.06 mm. near the head end, 0.14 mm. at the middle, and 0.12 mm. at the tail end. A specimen 10 lines long measured at the middle 0.1 mm. thick.

[October. 1878. No. 463. See Bibliography.]

Notice of a Tetrarhynchus.—Prof. Leidy stated that in the *Remora*, or Sucker, from our coast, presented this evening by Mr. Holbrook, he had found a curious parasite. This was inclosed in a compressed oval cyst, pearly white, thick-walled, and about half an inch long, tightly adherent to the intestine of the fish. The cyst contained a flask-shaped, translucent whitish sac, which was feebly contractile and furnished at the narrow end with two minute papillæ, which were slowly protruded and retracted. Within this sac-worm, coiled up about the center, was an opaque white worm or scolex, which proved to be a *Tetrarhynchus*. Removed and extended, it measured 7 lines long and was divisible about equally into a broad anterior body portion and a posterior narrow tail-like portion. The head was formed of a pair of obcordate bothria inclined from each other. Four long tortuous proboscides extended through the body and projected from the head. The projecting portions were successively elongated and shortened by eversion and inversion and were armed with recurved hooks. The hooks extended within half the length of the proboscides and, as they were everted and inverted, appeared like the streaming of liquid through narrow tubes. The tortuous proboscides at the bottom were continuous with as many elliptical pedestals placed at the back part of the body. The tail, about half the width of the body, was not segmented, but exhibited a disposition to assume this condition. The end was slightly tapering and occupied by a bell-shaped sinus opening externally and alternately contracting and expanding. The interior of the sinus was lined and its mouth thickly furnished with non-vibratile cilia. The species appeared to be undescribed and was named *Tetrarhynchus tenuicaudatus*.

[December. 1878. No. 466. See Bibliography.]

On Taenia Mediocanellata.—Prof. Leidy exhibited two specimens of tape-worms, *Taenia mediocanellata*, both retaining the head. These had been recently submitted to him for examination by Dr. James J. Levick and Dr. Walter P. Atlee. Tape-worm appears not to be a common affection with us. Several physicians, in extensive practice in this city, had informed him that they never had a case. During the last ten or fifteen years from one to two specimens annually had been submitted to him, but the present year he had seen five specimens. He had been surprised to find that all pertained to the species indicated. Formerly he supposed that our common

species was the *Tænia solium*, but later experience would indicate that the *Tænia medicocancellata* is the more common. The distinction between the two had been observed only comparatively recently, so that no doubt many specimens formerly attributed to the former actually belonged to the latter.

When the head is present the two species are readily distinguished. The *Tænia solium*, whose larval form is found in the "measle" of pork, has the head provided with a crown of hooks. *Tænia medicocancellata*, derived from beef and mutton, has a larger head, which is unarmed. The ripe segments are also usually readily distinguished in the two species. In the *T. medicocancellata* the ovaries are divided into many more pouches than in *T. solium*.

In Dr. Levick's case the man had been in the habit of eating raw buffalo meat. In one of the specimens exhibited the suckers of the head appeared as black spots, from the black pigment on their interior surface. The genital apertures were also black from the same cause. In the other specimen the head appeared less black from pigment about and around the position of the suckers, and the genital apertures do not appear black.

[November, 1878. No. 464. See Bibliography.]

On Donax Fosser.—Prof. Leidy remarked that last July, while on a visit to Cape May, N. J., he had observed on the beach, near low tide, east of the town, in many positions, vast numbers of the little lamellibranch mollusks, *Donax fosser*, of Say. It is well named the "Digger" from the ease and rapidity with which it digs its way into the sand by means of its powerful foot. It lives in the surface sand and is uncovered by the surf breaking on the shore, but instantly buries itself again as the waves retire. In some places the little Digger was so abundant that large patches reminded him "of barley grains lying on a matting floor," and they lay so thick as actually to interfere with one another in the attempt to bury themselves. As indicated by Mr. Say, they present two varieties, one in which the shell is white, the other in which it is straw-colored. The shells generally exhibit an interior livid tint in three rays, successively widening from before backward. The rays are sometimes feeble or nearly obsolete; the anterior one is the most persistent and the posterior one least so. The siphons are long and actively protruded and retracted, looking in their movements like wriggling worms. The Digger affords a bountiful supply of food to shore birds and fishes.

As is so frequently the case with crowded communities, the Digger

is much infested with parasites. From half a dozen to several dozen Flukes are found in the liver, and a ciliated infusorian in the branchial cavity.

The Fluke is a minute larval *Distomum*, with the following characters: Oval, obovate, clavate, or nine-pin like; head rounded, with a conspicuous nipple-like papilla on each side (which, when seen in the lateral view of the animal, gives the appearance of a beak to the head); tail obtuse, with a minute terminal pore. Integument finely granulate, the granules arranged in alternating transverse series. Oral acetabulum twice the size of the ventral, which is central or nearly so. Mouth large, unarmed. Pharynx minute, with a short, narrow gullet, ending in two pouch-like stomachs, which extend to the ventral acetabulum. A distinct body cavity, with no other contained organs than those just mentioned. A small orifice occupies the median line nearly midway between the acetabula; but no appearance of generative apparatus. Length of animal in the contracted state .24 mm.; width .15 mm.; length in the elongated state to .36 and .42 mm.; width .09 mm. Oral acetabulum .072 mm.; ventral acetabulum .042 mm. The species may be named *Distomum cornifrons*.

It is probable that this little Fluke undergoes its further development in some of the shore birds or fishes which use the *Dona v fosser* as food.

The infusorian infesting the Digger is a *Trichodina*, resembling that which is found on the *Hydra* or fresh-water polyp, and which is also stated by Stein to live on the gills of the pike and the fins of the stickleback. The *Trichodina* is bell-shaped, with a wreath of cils near the top and a circle of cils at the margin beneath. It is .048 mm. broad and from .035 to .036 mm. high. Though living on a marine mollusk, it too nearly resembles the *Trichodina pediculus* of fresh-water animals for him to think of giving it another name.

[January, 1879. Nos. 467, 468. See Bibliography.]

On Gordius and on some Parasites of the Rat.—Prof. Leidy exhibited a curious knotted mass of living hair-worms, *Gordius robustus?* which had been sent to him by Dr. S. T. Roman, of Conowingo, Cecil county, Md. The mass had been picked up in a gutter at the edge of a forest near Conowingo, on a rainy morning of December 15, 1878. It contained 52 male individuals and 7 females. The former ranged from 8 to 25 centimeters in length by $\frac{1}{2}$ to 2-3ds of a millimeter in thickness; the latter range from 14 to $19\frac{1}{2}$ centimeters in length by 1 millimeter in thickness. The females are

generally of much lighter color and more robust character than the males. In both sexes the body is most attenuated anteriorly, but in the female the body is nearly as thick at the posterior extremity as it is at the middle. Some of the smaller males are pale brownish-white, but most of them, from the smallest to the largest, are of various shades of brown to chocolate-brown. The females are pale brownish to darker brownish. In both sexes the head forms a convex, whitish eminence, encircled by a narrow black ring, from which a band of brown extends dorsally and ventrally along the body. The posterior end of the body is likewise of darker color than the part just in advance.

The tail of the male makes a spiral turn inwardly, and is furcate. The forks are short, curved, slightly divergent, blunt conical processes. Just in advance of their conjunction internally there exists an inverted crescentic fold of browner color than the contiguous parts, and immediately in advance is the genital pore. The interval of the caudal forks is smooth or free from papillæ.

The tail of the female appears truncated; is bluntly rounded, feebly clavate, or slightly thicker than just in advance, and nearly as thick as the middle of the body. It presents a terminal pore, marked by a brown spot and encircled with a brown ring.

Under a moderate magnifying power the brown integument is minutely mottled with whitish spots, and it exhibits fine longitudinal and diagonal striation. In sunlight it is beautifully iridescent, as in the earth-worm.

The worms are still quite lively. When disentangled and left alone they soon become again knotted together in a compact rounded mass, as at present, with the heads divergent and writhing so as to remind one of the head of the fabled Medusa.

Prof. Leidy then directed attention to several other specimens which had been sent to him for information. One of these is a bunch of tapeworms, 15 individuals of *Tenia diminuta*, from the intestine of a rat. The other is the liver of a rat with a multitude of cysts the size of large peas, containing *Cysticercus fasciolaris*. In a letter accompanying the specimens Dr. John R. Hewett states that last spring he had examined about 500 rats (*Mus documanus*) in Carroll county, Md., and only in half a dozen instances did he find the liver free from the parasite.

[February, 1879. No. 469. See Bibliography.]

On Bothriocephalus Latus.—Prof. Leidy exhibited specimens of a tapeworm which had been submitted to him for determination by

Dr. John T. Walker. The specimens consisted of about a dozen portions of what appeared to have been four or five individuals, all of them, unfortunately, without the head. They were discharged by a man aged 28 years, formerly a farmer, a native of Sweden, who came to this country about three months since. At irregular intervals during the last five years the patient passed fragments of a few inches of the worm. According to Dr. Walker, the collective measurements of the specimens presented he had estimated to be upwards of 100 feet. In their contracted condition, as preserved in alcohol, none of the mature segments measured over 4 mm. in length by 10 mm. in breadth. These are quite characteristic of *Bothriocephalus latus*. The egg pouches of the uterus, centrally situated, are rendered distinct from the ripe eggs, which gives to them a chocolate-brown appearance. The genital apertures are in the median line, nearer the anterior border of the segments. In *Tenia* the genital apertures are at the lateral margin of the segments.

The specimens were regarded as of special interest from the circumstance that they were the first of the *Bothriocephalus latus* that Prof. L. had had the opportunity of seeing from a person living in our country.

[September, 1879. No. 474 See Bibliography.]

Notices of some Small Animals on the Coast of New Jersey.—Prof. Leidy exhibited a valve of the beach-clam, *Mactra solidissima*, which he picked up among the numerous dead and bleaching shells of Brigantine Beach, N. J. It attracted his attention from its apparently having a fungus growing upon it. The fungus-like excrescence presented a remarkable resemblance to a *Polyporus* growing from the stem of a tree. It is an outgrowth from the lip of the shell, evidently dependent on an abnormal condition of the mantle of the living animal.

Prof. Leidy also stated that he had picked up on the beach at Atlantic City, N. J., another valve of the beach-clam, which had been recently cast on shore. The inner surface of the shell was covered with a multitude of the beautiful ciliated infusorian, *Friea ampulla*. The little creatures were still alive, and their curved, flask-like cases were of a deep green color.

Prof. Leidy further remarked that while at Atlantic City Mr. Phillips had directed his attention to two interesting animals recently collected. One of these he recognized as the *Bicidium parasiticum*, a parasitic anemone or Actina, found on the large jelly-fish *Cyanea arctica*, so frequently thrown on shore. The other was a

parasite of the shrimp, *Palæmonetes vulgaris*, which he recognized as the curious Isopod, *Bopyrus*. Many of the shrimps were infested with the parasite, the presence of which produced a conspicuous hemispherical tumor on one side of the carapace.

[October, 1879. No. 477. See Bibliography.]

On Amoeba Blattæ.—Prof. Leidy remarked that while perusing the communication of Prof. Bütschli on "Flagellata and other related organisms" (Beiträge zur Kenntniss der Flagellaten und einiger verwandten Organismen), in the Zeitschrift für wissenschaftliche Zoologie, 1878, 205, his attention was especially attracted by the description of a parasitic amoeboid living in the intestine of the cockroach, *Blatta orientalis*. It recalled to mind that he had observed the same creature a number of years ago in association with the ciliated infusorian he had described as *Nyctotherus ovalis*. At that time he had viewed it as a young form of a Gregarina, and had intended giving it and other parasites of the cockroach more critical examination, but failed to do so. The parasitic *Amoeba blattæ* is particularly interesting on account of its habit and its peculiar character. Prof. L. had recently examined some cockroaches, and found abundance of the amoeboid in association with *Nyctotherus ovalis*, *Lophomonas blattarum*, *Oxyurus gracilis*, and *O. appendiculatus* and an algoid plant.

The amoeboid, he thought, was worthy of a generic distinction from the true *Amoeba*, holding a position between this and *Protoamoeba*. From the former it differed in the absence of a contractile vesicle and, commonly, also of vacuoles, and in the want of differentiation of endosarc and ectosarc, and from the latter in the possession of a well-defined nucleus. He proposed for it the following name, with distinctive characters:

Endamoeba.—General character and habit of *Amoeba*: composed of colorless, homogeneous, granular protoplasm in the ordinary normal, active condition, without distinction of ectosarc and endosarc; with a distinct nucleated nucleus, but ordinarily with neither contractile vesicle nor vacuoles.

Endamoeba Blattæ.—Eine art Proteus. Seibold: Beitr. z. Natürungen d. wirb. Thiere, 1839, fide Stein.

Amöbenform. Stein: Organismus d. Infusionstheire, 1867, II., 345.

Amoeba Blattæ. Bütschli: Zeits. f. wis. Zoologie, 1878, xxx, 273, Taf., xv, Fig. 26.

Initial form globular, passing into spheroidal, oval, or variously

lobate forms, mostly clavate and moving with the broader pole in advance. Protoplasm finely granular, and when in motion more or less distinctly striate. Nucleus spherical, granular, with a large nucleolus. Distinct food particles commonly few or none. Size of globular forms 0.054 mm. to 0.075 mm. in diameter; elongated forms 0.075 mm. by 0.06 mm. to 0.15 mm. by 0.09. Parasitic in the large intestine of *Blatta orientalis*.

The *Endamoeba blattae* affords a good example of a primitive active nucleated organic corpuscle, or a so-called *organic cell without a cell wall*. In the encysted condition it would be a complete nucleated organic cell. *Endamoeba* may be recommended as a convenient illustration of a primitive form of the organic cell on account of its comparatively ready access.

[January, 1880. No. 480. See Bibliography.]

Notice of the Cruel Thread Worm, Filaria immitis, of the Dog.—Prof. Leidy directed attention to a specimen, presented by Mrs. Laura M. Towne, of Beaufort, S. C., consisting of the heart and part of one lung of a dog, containing thread worms. The right ventricle of the heart and the pulmonary artery contained a bunch of the parasites, and several also were contained in the lung. A similar specimen, with the ventricle literally stuffed full of worms, is preserved in the Museum of the University of Pennsylvania. The parasite was described thirty years ago, in the proceedings of this Academy, under the names of *Filaria Canis cordis* and *Filaria immitis* (see Proc. 1850, 118; 1856, 2, 55), and since has been repeatedly noticed by observers as infesting the dog in Europe, India, China, Japan, and this country.

[March, 1880. No 481. See Bibliography.]

On a Filaria Reported to have come from a Man.—Prof. Leidy exhibited a large thread-worm, which had been submitted to his examination by Dr. J. J. Woodward, U. S. A. It was recently presented to the Army Medical Museum, at Washington, by Dr. C. L. Garnett, of Buffalo, Putnam Co., W. Va. Accompanying this specimen is the copy of a letter from Dr. Garnett to Dr. Woodward, from which the following is an abstract: "During the winter of 1876 a man, a common laborer, aged about fifty, presented himself to me for treatment having a gleety discharge from the urethra, with a burning sensation during and after micturition. Previously he had been treated for gonorrhœa, and I prescribed accordingly. The patient, not improving, applied to other practitioners. In April,

1878, he came to me with a round, vivid-red worm, twenty-six inches in length (the specimen you now possess), and very active in its movements, instantly coiling up like a watch-spring on being touched. Having no work on helminthology for reference, the only description I found which appeared to answer to the worm was that of *Strongylus gigas*, in Niemeyer, vol. ii, p. 47. The patient is an illiterate man, with no motive for deception. He informed me that he discovered the worm protruding from his penis and drew it out without pain or difficulty. He was in much agitation and alarm about the occurrence, fearing, as he said, that "there might be more behind that one." For a few days previous to its passage his urine was of a milky hue and some time subsequently of a yellow cast and slightly tinged with blood and mingled with mucus. The man is truthful, and no doubt exists in my mind or in the minds of his neighbors as to the correctness of his statements. I regret exceedingly that I did not appreciate the scientific interest of the subject, and send you the specimen in a fresh state, but the busy routine of a country practitioner's life leaves no time for the study of other than subjects of practical value in one's every-day experience."

The worm preserved in alcohol is much coiled, of a clay color, and opaque or only feebly translucent, but more so at the head end. If it is really a human parasite it appears to differ from all those heretofore described, and also seems different from other known parasites. It certainly is neither *Eustrongylus gigas* nor is it the Guinea-worm, *Filaria medinensis*, though nearly related to this. Its characters are as follows: Body long, restiform, nearly uniformly cylindrical, smooth, shining, elastic, tough, without evident annulation other than transverse wrinkling, with the anterior extremity evenly tapering in the continuous head, the end of which is rounded and smooth or without appendages of any kind; the posterior extremity not tapering, with the caudal end incurved, bluntly rounded, without appendages and imperforate or without evident anal or genital aperture. Mouth a terminal pore without lips, papillæ, or armature of any kind. Pharynx cylindrical and opening into a straight cylindrical intestine, apparently ending in a blind pouch. Generative organs unobserved. Length of worm 26 inches; greatest thickness 1.5 mm. Width of head just behind the rounded extremity 0.375 mm.; opposite the commencement of the intestine 0.625 mm.; at the middle 1.5 mm.; at the incurved caudal extremity 1.5 mm. Length of oesophagus 1.125.

The worm, of exceedingly simple character, is clearly neither a *Gordius* nor a *Mermis*, and though apparently more nearly allied to

Filaria, a more intimate knowledge of its structure may prove it to be different. For the present it was proposed to distinguish it with the name of *Filaria restiformis*. (Drawing.)

[1880 NO. 486. See Bibliography.]

PARASITES OF THE TERMITES.*

GREGARINA.

Gregarina Termitis. Plate 52, Fig. 27.

A small *Gregarina* was once noticed in our Termite, and is represented in Fig. 27. The body is ovoid with the narrower end posterior. The head spheroid compressed from above downward. Length 0.06 mm.; head 0.018 mm. long, 0.03 broad; body 0.036 mm. broad.

Of the vegetal parasites found in association with the animal forms, within the small intestine of our Termite, there are two kinds; one a species of vibrio, the other an attached algoid, to which I formerly gave the name of *Arthromitus*.

VIBRIO.

Vibrio Termitis. Plate 52, Figs. 36-39.

Vibrios occur in great numbers as an associate of *Trichonympha* and *Dinenympha*. They resemble most nearly the *Vibrio serpens* of Müller, as described by Dujardin, Cohn, and others. Under the highest powers of the microscope at my command, one-tenth objective of Wailes, of Smith and Beck, and No. 11 immersion objective of Hartnack, they appear as immeasurably fine lines, usually ranging from 0.03 mm. to 0.045 mm. in length; but, in extreme, ranging from 0.015 to 0.06 mm. in length. They usually appear rectilinear and regularly undulant, with from three to five or six waves. They commonly remain stationary in position and undulate more or less rapidly, but they often advance or recede with variable rapidity, and sometimes become quiescent. Occasionally they bend at an obtuse angle while continuing to undulate, and sometimes they become zig-zag. Mostly they wave with regularity, sometimes irregularly, and occasionally the ordinary number of their waves is doubled. The smallest individuals, 0.015 mm. in length, are straight, but in movement become bent in the segment of a circle or become sigmoid.

The vibrios move in all directions among their associates. Not unfrequently numbers adhere together by one end and form radiating groups, as represented in Fig. 38.

* Journal Acad. Nat. Sci., Vol. 8, pp. 425-448. (Illustrated.)

[February, 1882. No. 489. See Bibliography.]

Filaria of the Black Bass.—Prof. Leidy stated that he had been told that the black bass, *Micropterus nigricans*, in some localities is much infested with a red thread worm. One procured in market a few days since for his table was found to be greatly infested. The worms were coiled in oval masses from the size of a pea to that of a large bean, and were situated beneath the skin, in the muscles, and under the membrane lining of the abdomen. The worm is cylindrical, slightly narrowed, and obtusely rounded at both ends, minutely annulate and otherwise smooth, pale red, bright red, or brownish red, translucent, with the darker red or brownish intestine and the white cesophagus shining through. Mouth a small pore, unarmed; anus a transverse elliptical pore, terminal. Oesophagus long, capacious, cylindrical, straight or somewhat tortuous, slightly expanded below where it is constricted from the intestine, which is likewise expanded at the commencement, and ends in a short, more translucent rectum. Ovarium and ova indistinctly seen. Length from 3 to 6 inches by half a line in diameter.

The worm appears to be a *Filaria*, but the determination of the species was left for more extended observation.

[March, 1882. No. 491. See Bibliography.]

On Balanoglossus, etc.—Prof. Leidy stated that in a recent trip to Atlantic City he had observed the singular worm *Balanoglossus aurantiacus*. It occurs in moderate numbers along the shore of a pond between the beach and the lighthouse. In the same position he had collected *Solenensis*, specimens of which were presented this evening. As this occurred in considerable number, he had procured a sufficient quantity to try it as an article of food, and had found it to make excellent soup. In the vicinity he had picked up a number of specimens of *Actinia rapiformis*, which had been recently thrown upon the beach. On a former occasion, at Atlantic City, he had observed another Actinia, the *Bicidium parasiticum*, which is parasitic on the large jelly-fish, *Cyanea arctica*, so frequently thrown on shore during the summer.

[April, 1882. No. 492. See Bibliography.]

On Sagitta, etc.—Prof. Leidy stated that in a recent trip to Atlantic City, N. J., he had for the first time met with the singular worm *Sagitta*. It occurred in large numbers in the same pond in which he had previously noticed *Balanoglossus*. Whether it was

there at the time of his former visit he was unable to say, as the animal is as transparent as the water in which it lives, and may easily escape observation. His attention was accidentally directed to its discovery. Along the edge of the pond there were numerous linear white bodies, flaccid and motionless, which he at first took for fragments of a bleached alga. From the uniformity of their size he stooped to examine them more closely, when he noticed others in the water, more transparent, lying on the sand and occasionally moving suddenly and so actively as to send a little spray above the surface. On transferring some of these bodies to a vial he detected their nature. Subsequently the water was seen to swarm with the little creatures. They were exceedingly sensitive, and quickly die after removal. In life they were perfectly transparent and colorless, and move actively at intervals with a sort of spasmodic jerk, bending the tail downward and darting forward. After death they become flaccid, dull, and white, and hence the appearance of the multitude of dead ones on the shore.

The *Sagitta* is interesting as being one of those peculiar animals which have puzzled naturalists as to its exact relative position. It is now usually regarded as the representative of an order of worms with the name of *Chaetognatha*.

A species, *Sagitta elegans*, has been described by Prof. Verrill as occurring at Wood's Holl, Vineyard Sound, and Gay Head, on the New England coast, and he refers to a second undetermined species occurring in Vineyard Sound.

The *Sagitta* of Atlantic City appears to differ from the former, and also from all other described species found elsewhere, and may be readily distinguished from them by its greater number of mandibular hooks. It may be characterized as follows:

Sagitta Falcidens.—Animal transparent, colorless; body compressed, elongated fusiform, with two pairs of lateral hemi-elliptical fins, separated by intervals from each other and the broad obcordate caudal fin, which is truncated posteriorly. Head obcordate, about as broad as it is long. Pre-oral series of spines, 6 or 7 in each, minute; postoral series, 18 in each, successively decreasing. Mandibular hooks, from 11 to 14 in each series, usually 12, besides an immature one, scythe-shaped, yellowish brown in color. Length about 3-4ths of an inch, width $1\frac{1}{2}$ to 2 mm. Head 1 mm.; caudal fin 1.5 to 1.75 mm. wide. Mandibular hooks 0.75 mm. long.

At the same time as previously numerous mounds of the *Balanoglossus aurantiacus* were observed. There were also noticed in the same pond many projecting tubes of sand, which were found to

contain *Clymena torquata*. Further, several specimens of *Glycera americana* were collected. On the shore of the pond in one place *Donax fosser* appeared to have its residence, and among *Solenensis* a single living *Solecurtus gibbus* was found.

[May, 1882. No. 493. See Bibliography.]

On some Entozoa of Birds.—Prof. Leidy directed attention to some specimens presented by Joseph Wilcox, recently collected by him in Florida. One of the specimens is the head of a Snake-bird, *Plotus anhinga*, with a worm in sight, lying upon the brain, while several other detached worms of the same kind lay at the bottom of the vial. The worm in its singular habitation was discovered by Prof. Wyman in Florida in 1861 and 1867, an account of which is given in the Proceedings of the Boston Society of Natural History, volume 12, 1868. Prof. Wyman had kindly presented Prof. Leidy with a specimen of the head of the Snake-bird, with the worms lying on the brain. This he had valued as a memento of his friend, but it had unfortunately been lost in the fire at Swarthmore College last autumn. Prof. Wyman states that the parasites were found coiled on the back of the cerebellum between the arachnoid and pia mater. The number varied from two to six or eight, or even more. In nineteen birds they were detected in seventeen. Mr. Wilcox found the parasites in four out of six birds examined. In the present specimen of a head a single worm is enclosed between the two laminae of the dura mater over the position of the interval of the cerebrum and cerebellum. As the parasite appears not to have been named, it was suggested that the name of its discoverer should be associated with it under the name *Filaria wymani*.

The accompanying four vials contain numbers of worms obtained from the stomachs of the Snake-bird, the Cormorant, *Graculus dilophus*; the White Pelican, *Pelecanus trachyrhynchus*, and the Brown Pelican, *P. fuscus*. All prove to be of the same species, the *Ascaris spiculigera*. Specimens of these were also formerly obtained by Samuel Ashmead in Florida from the White Pelican (Proc. Ac. Nat. Sci., 1858, 112). The same likewise have been submitted for examination by Dr. Elliott Coues, who procured them from the White Pelican on the Red River of the North. See Birds of the Northwest, 1874, 587.

[May, 1882. No. 495. See Bibliography.]

On Bacillus Anthracis.—Prof. Leidy stated that Dr. Robert Gladfelter, veterinary surgeon, had submitted to his examination a bottle

of blood from a cow. The animal, apparently well on Wednesday, May 10, and milked the same evening, died the next morning. The cause was not clear, but was suspected to be the result of anthrax, charbon, or splenic fever. During the past year a number of cows in the same herd had died in a similar manner in Salem Co., N. J. A post-mortem examination was made the following day, and the abdominal viscera were found much congested, especially the spleen, which was gorged with blood. The specimen of blood obtained from the spleen was examined the next day, Friday. It teemed with bacteria, the peculiar form, *Bacillus anthracis*, which is now viewed by most competent authorities as the cause of the frightful affection known as anthrax or splenic fever. The bacilli were actually more numerous than the blood corpuscles, which appeared unchanged. The bacilli were completely motionless, straight, bent, or zigzag filaments; in the latter condition in pairs or more segments. They measured from 0.006 to 0.042 mm. in length; usually from 0.012 to 0.03 mm. Kept for some days in the blood, the filaments underwent division into little chains in two, three, or more dumb-bells, which measure about 0.005 mm., or into isolated micrococci-like particles about 0.0015 mm. Many, however, of the filaments did not resolve themselves into these minute particles, but appeared only to grow in length and divide into segments of about 0.012 mm. in length.

[**May, 1882. No 496. See Bibliography.]**

On Enchytraeus, Distichopus, and their Parasites.—Prof. Leidy remarked that occasionally in lifting a flower-pot, or in stirring the earth within, attention is sometimes attracted by the sudden wriggling of a little white worm disturbed from its rest. In the *Archiv fur Anatomie*, 1837, Henle has given an elaborate description of the worm, and named it *Enchytraeus* in reference to its familiar habitation. The little pot worm is common in our vicinity, especially in damp forests under decaying leaves and timber. It was first noticed in 1773 from Denmark by O. E. Muller, and in 1880 from Greenland by Fabricius. It has also been observed in France and Germany, and therefore the little worm appears to extend over the northern parts of Europe and America.

The same worm I have found in the meadows of Atlantic City, New Jersey, in the usual haunts of *Melampus bidentatus* and *Orchestia agilis*. In mature specimens, about three-fourths of an inch in length, the girdle is well produced, and the body has ten setigerous segments in advance of it and about forty-five behind it. The short-

pointed setapeds in four longitudinal rows are in fascicles of three or four to each in advance of the girdle and two or three to each behind it.

In the *Enchytraeus* of our forests I have repeatedly observed an infusorial parasite occupying the body cavity, sometimes in considerable numbers, mingled with the normal discoid corpuscles. I propose to name it *Anoplophrya modesta*. In the *Enchytraeus* of the meadows of Atlantic City I observed a different infusorian occupying the same cavity, remarkable for its great proportionate length. This I propose to name *Anoplophrya funiculus*.

Wishing to ascertain whether the latter did not likewise infest the *Enchytraeus* of our neighboring forests I recently collected a number of little worms at Media, Delaware county, Pa. These I obtained from beneath a stone lying in my path to Swarthmore College. They appeared to be robust specimens of *Enchytraeus vermicularis*, for which I took them to be. Investigation at home proved them to be different and generically distinct from previous known forms. The worms possess but two rows of setapeds, instead of four, as in most others of the family. Hoffmeister and Gruby described the genus *Phrcoryctes* as having only two rows of setapeds, but Leydig has shown this to be an error. In view of the error, I carefully repeated my examination of the little worms from Media, and am convinced that they possess two rows of setapeds, while in *Enchytraeus* I always found four. So much do the former otherwise resemble the latter that it would appear as if they formed a genus directly evolved from *Enchytraeus* merely by the suppression of a pair of the four rows of setapeds.

The new genus presents the following characters, and may be indicated by the accompanying name:

Distichopus.—Form and color as in *Enchytraeus*, with a well-produced girdle. Setapeds in a single row on each side ventrally, in divergent fascicles of four in advance of the girdle and of three behind it.

Distichopus Silvestris.—Body cylindrical, white, translucent, with a well-produced girdle of whiter color. Upper lip short, conical blunt; anal segment thicker than the penultimate, brownish and punctate; anus quinquiradiate. Ten setigerous segments in advance of the girdle, with fascicles of usually three or four setapeds; fifty-five setigerous segments behind the girdle, with usually two or three setapeds. Oral and anal segments without setapeds. Setapeds shorter and stouter than in *Enchytraeus vermicularis*, curved at the root, swollen at the middle, and straight towards the point. Length from nine to fifteen lines.

I observed no infusorian in *Distichopus*, but in most of those examined there were found minute Gregarines allied to the *Monocystis* of the earth worms, *Lumbricus*. This parasite was perfectly quiescent, and was especially remarkable for its frequently containing a variable number of curved elliptical bodies, which I suspect to be spores. Viewing it as a species of *Monocystis*, it may thus be briefly characterized :

Monocystis Mitis. *Gregarina Enchytræi?* Kolliker. Body fusiform, tapering posteriorly and usually acute, anteriorly obtuse or produced into a short mammilla; contents of the usual granular protoplasm as in gregarines, with a central spherical nucleus and nucleolus. Size ranging from .03 mm. to .12 mm. in length. In the smallest individuals the nucleus was indistinct and in some appeared to be absent. The larger ones mostly contained what I supposed to be spores. These are curved elliptical bodies .015 mm. long by .0045 wide, and were collected in a group of usually two or three to seven or eight, sometimes in advance of the nucleus and sometimes behind it. (Drawing.) The two *Anoplophrya* above indicated have the following characters :

Anoplophrya Modesta. *Leucophys.* Jour. Ac. Nat. Sc., 1850, 49, pl. 2, fig. 17. Elongated elliptical, anteriorly rounded, posteriorly somewhat truncated, usually from three to five times the length of the breadth; nucleus axial, cylindrical, straight, extending about two-thirds the length of the body; contractile vesicles variable in number and usually in two longitudinal rows. Length from .048 to .12 mm.; breadth .018 to .024 mm. In state of transverse division the pairs range from .054 to .15 mm. in length. Common and numerous in the body cavity of *Enchytræus vermicularis*. (Drawing.)

Anoplophrya Funiculus.—Long, narrow, and ulna-like in shape, from twenty to thirty times the length of the breadth; anterior extremity slightly wider and very obliquely truncated and slightly depressed; posterior extremity bluntly rounded. Nucleus axial bristle-like, appearing as a double continued line reaching from the posterior end of the body and tapering to a single line in the posterior part of the same. Contractile vesicles minute, in two rows, variable in size and usually occupying the posterior part of the body. Length 0.42 to 0.6 mm. by 0.018 to 0.024 mm. wide. Young individuals 0.15 mm. long by 0.024 wide were tapering in front and obtuse, while they were wider and rounded behind. Inhabiting the body cavity of *Enchytræus vermicularis* from the meadows of the Atlantic coast of New Jersey. (Drawing.)

In an earth worm, *Lumbricus*, species undetermined and occurring

under logs in the forests in the vicinity of Philadelphia, I detected another species of the above, which may be distinguished as follows:

Anoplophrya Melo.—Oval or ovoid, scarcely twice the length of the breadth, with the narrower pole mucronate; nucleus axial, cylindrical, sigmoid, about two-thirds the length of the body; contractile vesicles, usually one or two or none, large. Length 0.048 mm. to 0.08 mm.; breadth 0.032 to 0.04 mm. Pairs in state of transverse division 0.08 by 0.036 mm. to 0.084 by 0.04 mm. Inhabiting the body cavity of *Lumbricus*? (Drawing.)

[September 1882. No. 499. See Bibliography.]

On the Tobacco-worm, etc.—Prof. Leidy exhibited a collection of tobacco-worms, the larvæ of *Sphinx carolina*, which he had obtained two days ago from a tobacco field near Columbus, N. J., where they were very abundant and had proved a great pest in the cultivation of tobacco. The worms collected presented a number of well-marked varieties, which were supposed to be all of the same species. The principal ones were indicated as follows:

1. Pea-green or yellowish-green, more or less finely hairy, with lateral oblique white bands bordered above with black dots, which extend to the dorsal median line; head bright pea-green, dorso-caudal spine red. This is the most common variety.
2. Pea-green, smooth, with lateral oblique white bands joined in front below by horizontal white bands, so as to form a series of V-like marks, the apex of each joining the lower limb of the one in advance; head green, dorso-caudal spine black.
3. Grass-green, smooth, with lateral white V-like marks as in No. 2, the oblique bands bordered above by blackish or brownish; upper part, especially in front, more or less dotted with white; head green, with a pair of black bands on each side; dorso-caudal spine black.
4. Yellowish-green annulated with narrow black lines, with lateral white V-like marks, the oblique bands bordered above with black; head bright pea-green, dorso-caudal spine red.
5. Dull green, with more or less brown dorsally, and dotted with white, the dots more or less tuberculate, but otherwise smooth, with lateral white V-like marks, the oblique band bordered above with brown ascending to the dorsal median line; head green, with a lateral pair of black bands; dorso-caudal spine black.
6. Chocolate-brown to nearly black, smooth, with white dots dorsally and anteriorly, with lateral white V-like marks; head shining black on each side, dorso-caudal spine shining black.

7. The same as No. 6, with lateral red V-like marks.

Among these more marked varieties others were noticed which were more or less of an intermediate character. The most common variety was that which was least distinguishable in color from the animal's location, the tobacco leaf, so that it was especially favored in its preservation.

Prof. Leidy further remarked that the past season had appeared to be favorable to many of the Lepidoptera. Our shade-trees had been greatly ravaged by the *Orgyia*, many of the poplars had suffered from the *Closteria inclusa*, and he had observed an unusual quantity of the Ailanthus silk-worm, *Attacus cynthia*, upon the Ailanthus trees. The latter was introduced here in 1861 by Dr. Thomas Stewardson.

[October, 1882. No 500. See Bibliography.]

ROTIFERA WITHOUT ROTARY ORGANS.

The Rotifera or Wheel-animalcules form a small class, abundant in kind and found almost everywhere in association with Algæ, and with Infusorians, to which they were formerly considered to belong. Later they have been recognized as not having the simple cell structure of the latter, and for a time were regarded as pertaining to the Crustacea. They are now commonly looked upon as belonging to the group of worms, but their relative position cannot yet be considered as positively determined. They generally possess a chitinous integument, with a more or less annulate disposition or tendency to articulate division, but they are destitute of limbs. Some are provided with a carapace, and recall crustacean forms, but in other points they exhibit but little likeness to them. Their usually striking characteristic, the rotary disks, from which they are named, is not possessed by any well-marked Crustacean. Among the Rotifera, however, there appear to be some which do not possess the rotary organs, at least in the mature condition, and yet in all other respects the animals conform in structure with ordinary forms.

* * * * *

[The above is extracted from the original paper for reference. The whole paper is not included.]

[October, 1882. No. 501. See Bibliography.]

A New Infusorian Belonging to the Genus Pyxicola.—Prof. Leidy exhibited drawings of an infusorian, a species of *Pyxicola*, which

appeared to be different from those previously described. It is of frequent occurrence, attached to the tubes of *Plumatella*, *Urnatella*, and *Cordylophora*, on stones in the Schuylkill River below Fairmount dam. In shape it resembles *Pyxicola pussilla* and *P. affinis*, fresh-water forms of England, but is annulate, as in *P. socialis*, a salt-water form. It is represented in Figs. 8 and 9, pl. II, and presents the following characters: (Drawing.)

Pyxicola Annulata.—Lorico urceolate, slightly curved, inflated toward the middle, tapering below, cylindrical and feebly contracted at the neck, and with the aperture oblique and circular; variably annulate, mostly at the neck, often at the middle; color, chestnut brown, but colorless when young. Pedicle short, always colorless. The contained animalcule is of the usual shape, with an attached operculum, which is of the same color as the lorica and is protruded beyond this when the animal is fully extended. Length of lorica 0.52 to 0.792 mm.; breadth 0.02 to 0.0264 mm.; length of pedicle .004 to .008 mm.

[October, 1882. Nos. 502 and 504. See Bibliography.]

Actinosphaerium Eichhornii.—Prof. Leidy remarked that he had noticed in an aquarium what appeared to be eggs adherent to the edges of the leaves of *Vallisneria* from the Schuylkill River. On examining the egg-like bodies with a lens they were observed to be covered with delicate rays. On transferring some of the bodies to the field of the microscope, they proved to be giant specimens of the larger sun-animalcule, *Actinosphaerium eichhornii*. They measured from three-fourths to one millimeter in diameter independent of the rays, which extended from one-fourth to half a millimeter more. One of the smaller individuals contained four water-fleas, *Daphnias*, a third of a millimeter long, and one of the larger contained six of these. The *Actinosphaerium* appears to be tenacious of life, several specimens having been retained alive and in good condition for three days in a drop of water in an animalcule cage. They had discharged the *Daphnias*, but retained their original size. One of oval form measured 1 mm. long by 0.75 mm. broad. The smaller ones measured 0.75 mm. in diameter. After another day they appeared in good condition, but the rays were contracted so as to be about half the original length, and many had a minute granular ball at the end, apparently effete matter thrown off from them. At this time the animalcules were returned to the aquarium.

[February, 1883 No. 509. See Bibliography.]

On the Reproduction and Parasites of Anodonta fluviatilis.—Prof. Leidy directed attention to a basketful of living fresh-water mussels, *Anodonta fluviatilis*, which were obtained for him through the kindness of Rev. Jesse Y. Burke, and are now placed at the disposal of members who wish to have them. They are fine, robust specimens, the larger ones measuring 6 inches in length by 3 inches in height and almost 2½ inches thick. They were obtained from a little pond occupying an old marl pit near Clarksboro, Gloucester Co., N. J.

These mussels appear to be exceedingly prolific. The pregnant females have the branchial uteri, as they have been appropriately named by Dr. Isaac Lea, enormously distended with perfected embryos. These appear with a cinnamon-brown shell, having a conspicuous spinous tooth or hook to each valve, and are furnished with long byssal threads. Wishing to ascertain the proportionate amount of embryos, the following plan was adopted: In an individual 6 inches long the soft parts were weighed and found to be 135.44 grammes. The branchial uteri weighed 64 grammes and the inner gills 7.34 grammes. Supposing the latter to be the same weight as the outer gills, free from embryos, this weight subtracted would leave 56.66 grammes as that of the embryos and 78.78 grammes as the weight of the rest of the animal. In another specimen, in which the weight of the soft parts was 113.75 grammes, the branchial uteri weighed 45.5 grammes and the inner gills 5.2 grammes. Subtracting the weight of these would leave 40.3 grammes as the weight of the embryos and 73.45 grammes for the rest of the animal. In another specimen by weight and counting the embryos in a milligramme were estimated to be 1,280,000.

The mussels are infested with many water mites creeping about among the gills. The young of the same in various stages were observed imbedded in the mantle. The mite appears to be identical with the species *Ixodes ypsiloniphorus*, which is a parasite of the common mussel, *Anodonta cygnea*, of Europe. It was discovered and described just 100 years ago, under the name *Ixarus ypsiloniphorus*, by Dr. Christopheri Gottlieb Bonz (Nova Acta Phys. Med. Acad. C. L. C. Nat. Cur., Nuremberg, 1783, 52, Tab. 1, figs. 1-4). It is described and figured by Pfeiffer, with the name *Limnochares anodontae* (Naturg. deutscher land und suss-wasser Molusken, 1821, Taf. 1, fig. 12); by Dr. Karl Ernst v. Baer, under the name of *Hydrachne concharum* (Nova Acta, Bonn, 1826, 590, Taf. XXXIX, fig. 19); by P. J. Van Beneden (Mem. de l' Acad. R. des sciences de

Belgique, xxiv, 1850), and by Ed. Claparede (Zeits. f. wiss. Zoologie, 1868, 445).

Dr. Bonz's description, referring chiefly to the form, color, and marking of the mite, applies to ours, and, further, he thought the description of the details of Claparede applies sufficiently well to the same.

The characters of our mite are, briefly, as follows:

Body ovoid, black, with a sulphur-yellow median line, often more or less interrupted, forked in front and ending in an angular spot behind. The yellow marking divides the black into a pair of lateral reniform spots and an anterior irregular lozenge spot. Sides brown, from the eggs shining through. Head gray, with dumb-bell eye spots. Limbs gray, translucent, with the chitinous investment bluish-black, hirsute, ending in pairs of double falcate unguis. Terminal joint of the palps ending in three minute uncinate denticles. Anal plates of the females usually with about 18 to 20 acetabula to each. Length of body 1.375 to 1.75 mm.; breadth 1.125 to 1.5 mm. Inhabits the branchiae and mantle of *Anodonta fluviatilis*.

The colors depend mainly on the contents shining through the transparent chitinous investment, which, under reflected light, exhibits a bluish-black tint. Commonly the black color is intense, and in alcoholic specimens the whole body is black. In several individuals the black passed into a chocolate hue. Dr. Bonz describes the European mite as black, with the median dorsal mark pale yellow; Pfeiffer as red-brown, with a citron-yellow mark, and Beneden says it shows a Y in white, from which it was named.

The number of acetabula to the anal plates is variable. In one mite he found 23 to each plate, in a second 22 to each, in a third 22 to one and 17 to the other, and in a fourth 18 to one and 17 to the other. Claparede gives from 15 to 20 as the number to each plate in the European mite.

The variations of our mite from the characters given of the European mite are such as occur among individuals of either. He therefore saw nothing distinguishing ours as a different species. Claparede describes another mite which infests the European Unios, which he distinguishes under the name of *Atax bonzi*. The speaker had also observed a different mite, infesting the common mussel, *Unio complanatus*, of the Delaware river. Of this mite he exhibited a drawing made in November, 1854. He suspected it to be the *Atax bonzi*, but the question can only be more positively answered

after the examination of certain details, which he hoped soon to have the opportunity of making.

If our two parasitic mites are identical with those of European mussels, it not only makes it appear probable that they are of common origin, but renders it the more probable that this is likewise the case with their hosts, even if these are not regarded as of the same species.

Professor Leidy also exhibited a collection of body-lice, *Pediculus vestimenti*, from Jews of Odessa, Russia, presented by Dr. A. G. Stratton. They range in size from 1.25 to 3.875 mm. in length, and appear in no respect to differ from those found on natives of our own country.

[November, 1883. No. 513. See Bibliography.]

MANAYUNKIA SPECIOSA.

At the time of the discovery of the pretty polyzoan, *Urnatella gracillis*, of which a description is now in course of publication in the Journal of the Academy, I found an equally interesting little annelide, of which I gave a brief notice in 1858, published in the Proceedings for that year, page 90, under the name of *Manayunkia speciosa*. The two were found in company together attached to some stones, in the Schuylkill River, at Fairmount, Philadelphia. They seem fitting associates, for while *Urnatella* is nearly related with the marine *Pedicellina*, *Manayunkia* is closely related with the marine annelide *Fabricia*. *Manayunkia* has proved to be less frequent than *Urnatella*, nor have I found it elsewhere than in the locality named. Recently several specimens were submitted to my examination by our fellow-member, Mr. Edward Potts, who found them attached to a fragment of pine bark in Egg Harbor River, New Jersey. Independent of the interest of finding the worm in a new locality, the specimens have enabled me to complete an investigation of the animal so far as to prepare the following description, though I have to regret that the material has been insufficient to allow me to clear up several important points. I have had the opportunity of comparing *Manayunkia* with a species of *Fabricia* living on our coast, and have found the two to be so nearly alike that I am prepared to hear it questioned whether the former should be regarded as generically distinct from the latter.

Manayunkia forms a tube of mud, which it occupies. The tube is composed of the finest particles, agglutinated by a mucoid secretion of the worm. It is cylindrical, straight or bent, mostly even or

slightly uneven on the outside, and sometimes feebly annulated. It is attached partly along its length to fixed objects, with the greater part free, directed downward and pendent. Most specimens observed were single, but several were found in which two or three tubes were conjoined, and in one instance five tubes, with remains of others, were given off in a candelabra-like manner from a common stem, as represented in Fig. 2, plate IX. From the open mouth of the tube the worm protrudes its head and spreads its crown of ciliated tentacles in the same manner as in more tubicolous annelides. The simple tubes range from two to four lines in length by the one-fifth to the one-fourth of a line in width.

Manayunkia is very sensitive, and on disturbance withdraws deeply into its tube, so that half the length of the latter may be removed before reaching the worm. The little creature clings tightly to the inside of its habitation, apparently mainly by means of the minute podal hooks of the posterior segments of the body.

The mature worm (Fig. 1) is from three to four millimeters in length by about one-fourth of a millimeter in breadth, and is divided into twelve segments, including the head. The color is translucent, olive green, with the cephalic tentacles of a slightly brownish hue. As the worm shortens, the segments become more bulging laterally and the constrictions deeper; in elongation the segments become more cylindrical and the constrictions less marked. When the worm is elongated it is of nearly uniform width for about three-fourths of the length, and then slightly tapers to the end, or is a little widened again in the two segments before the last. The head is about as broad as it is long, and is surmounted by a pair of lateral lophophores supporting the tentacles. Its border above projects dorsally into a short rounded process. The succeeding four segments of the body are about as broad as they are long, and nearly of uniform size: the next one is somewhat longer than those in advance. The seventh segment, in all the mature worms observed, greatly exceeded any of the others. It was usually twice the length, and differed from them in having an abrupt expansion at the fore part, which suggested the production of a head prior to the division of the worm; a process, however, if it occurs in *Manayunkia*, I had not the opportunity of observing. The succeeding segments, smaller than the anterior ones, differ little in size, except the last two. The terminal segment abruptly tapers from above its middle to an obtusely rounded extremity. When the worm protrudes from its tube, the lophophores are reflected from the head, and they exhibit a double row of tentacles extending forward. The number of ten-

tacles varies with the age of the worm, but at maturity there are usually eighteen for each lophophore. They are of moderate length, and of uniform extent, and measure about half a millimeter. Two of them internally, one for each lophophore, are rather longer and larger than the others, and are rendered conspicuous by a large vessel filled with bright green blood. The tentacles are invested with ciliated epithelium, with actively moving cilia, and in all respects bear a close resemblance to those of the polyzoa. In the allies of *Manayunkia* they are regarded as branchial appendages, and usually named cirri; and although this is unquestionably correct, as in the case of the corresponding organs of the polyzoa, they perform a varied function, and may, with equal correctness, be called tentacles.

When *Manayunkia* is about to withdraw into its tube, the lophophores approach, and, together with the tentacles, form a close longitudinal fascicle. Along the lophophores, at the base of the tentacles, there is a row of half a dozen or more brownish pigment spots, resembling eyes, but not having the usual constitution of such organs. The segments of the body of *Manayunkia*, succeeding the head, are furnished on each side with a fascicle of locomotive setæ, which is divided into two portions, one usually consisting of shorter setæ than the other. The fascicles, when most protruded, project from a papilla, which disappears with the partial retraction of the former. They are projected directly outward or in a slanting manner either forward or backward, and are moved in the same manner and by the same arrangement of muscles as in other chaetopods. The number of podal setæ is from four to ten in each fascicle. In several mature individuals the numbers in the different segments were as follows: 8 to 10 setæ in the first to the sixth segment; 6 to 7 in the three succeeding ones, 4 or 5 in the tenth, and 3 or 4 in the last segment.

The setæ, Figs. 3, 4, of the anterior segments are longest and range from about 0.15 to 0.25 mm. in length. They consist of a long, straight rod, with a linear-lanceolate blade, tapering into a long filament. The rod varies little in length in the different setæ, but the blade varies considerably in this respect. The blade is more or less bent from the rod and is longest in the long setæ.

Except the head and the first setigerous segments, the others are provided on each side with a fascicle of podal hooks, which are situated ventrally behind the bottom of the podal setæ. The hooks are 4 or 5 in each fascicle in the setigerous segments from the second to the eighth inclusive, and are very different from those of the

succeeding segments. The podal hooks, Fig. 5, of the anterior segments are about 0.05 to 0.06 mm. long, and consist of a long, curved handle, ending in a small recurved hook.

The podal hooks of the posterior three setigerous segments form close transverse rows, Fig. 6, of variable number, from 9 to 24 in each row. The hooks are minute, and measure from 0.025 to 0.03 mm. long. They consist of a broad handle, ending in a lateral comb-like extremity, as represented in figure 7.

The number of podal setæ and podal hooks is more or less variable in the corresponding segments of different individuals, and frequently, also, on the two sides of the segments of the same individual. The difference is due sometimes to the accidental loss of some of the appendages; sometimes, probably, to circumstances interfering with their development. In several specimens the following differences were observed:

SPECIMEN 1.

First segment, 6 and 8 setæ.

Second to fourth segment, inclusive, 8 to 10 setæ and 4 to 5 hooks.

Fifth to eighth segment, inclusive, 6 to 8 setæ and 4 to 5 hooks.

Ninth segment, 6 setæ and 9 to 22 hooks.

Tenth segment, 4 setæ and 12 and 18 hooks.

Eleventh segment, 3 and 4 setæ and 12 hooks on each side.

SPECIMEN 2.

First segment, 8 setæ on each side.

Second to sixth segments, inclusive, 8 setæ and 4 hooks on each side.

Seventh and eighth segments, 6 or 7 setæ and 4 hooks, except on one side of the eighth segment, in which another fascicle of 6 setæ substituted the usual fascicle of hooks.

Ninth segment, 6 setæ on each side and 9 and 20 hooks.

Tenth segment, 4 and 5 setæ and 13 and 16 hooks.

Eleventh segment, 3 and 4 setæ and 12 hooks on each side.

SPECIMEN 3.

First segment, 8 setæ each side.

Seven succeeding segments, 6 to 10 setæ and 3 to 4 hooks each side.

Ninth segment, 7 setæ and 24 hooks each side.

Tenth segment, 3 setæ and 18 hooks, but on one side the latter were all imperfect, mostly with the comb undeveloped.

Eleventh segment, 2 setæ and 14 hooks each side.

In the last specimen the rows of 24 hooks in the ninth segment measured 0.08 mm. wide; the rows of 18 hooks of the tenth segment 0.072 mm. wide, and the rows of 14 hooks of the last segment 0.06 mm. wide. The height of the rows corresponding with the length of the hooks was 0.025 mm.

The intestinal canal of *Manayunkia* is of extreme simplicity, consisting of a median tube alternately dilated within the segments and contracted in the intervals of the latter, without any other conspicuous division into more distinct portions. The widest expansions are within the fourth to the seventh segment, inclusive, but are also variable in these. Afterwards the intestine becomes narrower to the anus, which opens ventrally in the last segment. The mouth is funnel-like, capacious, and without armature of any kind. Along the intermediate two-thirds of the canal the walls are of a yellowish brown hue. Within the intestine in the seventh segment, and within the terminal portion, active ciliary motion was observed. The intestine, as usual in other annelides, is connected by thin diaphragms to the wall of the body cavity in the intervals of the segments. The intervals are occupied with liquid with multitudes of floating corpuscles.

The ovaries, with ova in different stages, occupy the fourth to the sixth segment, inclusive. Within the lower part of the head, extending thence into the third segment on each side, there is a large elliptical organ, which I have suspected to be the testicle, though I did not examine its structure.

I was greatly puzzled in the attempt to ascertain the arrangement of the vascular system of *Manayunkia*, and am in doubt as to the following explanation I give of it: The blood is of a bright green color, and in many positions serves clearly to define the course of the larger vessels. As represented in figure 1, the chief blood vessels appear to be a large one on each side of the intestinal canal, closely following the course of this, so as to seem to form a green coat to it. In each segment of the body the vessel gives off a pair of lateral branches, apparently uniting in a loop. In the head the two main vessels leave the sides of the intestine, and, after forming a close flexure or a sinus at the base of each lophophore, proceed outward through the interior of the larger pair of tentacles. In viewing the worm in any direction, the two main vessels so constantly appeared at the sides of the intestine that I at first took them for the walls of

the latter itself. The condition I did not comprehend until I found an explanation in the following paragraph in Claparede's *Recherches sur la structure des Annelides Sédentaires*, Geneva, 1873, page 76: "M. de Quatrefages has discovered that in certain *Serpuliens*," to which family *Fabricia* and *Manayunkia* belong, "the intestinal canal is enclosed in a lacuna or rather a veritable sheath taking the place of a dorsal vessel." Claparede adds from his own observations the statement "that a number of the sedentary annelides present the same peculiarity of having the intestine included in a vascular sheath playing the part of a dorsal vessel." In this view the two chief vessels, in figure 1, at the sides of the intestine, are to be regarded as sections of the vascular sheath enclosing the latter.

The principal movement observed in the vessels of *Manayunkia* consisted in an incessant pumping of blood into those of the two larger tentacles, alternating with contraction and partial expulsion of blood from the same.

The nervous system of *Manayunkia* I did not attempt to investigate. A well-developed eye occupied the head at the side of the gullet. It exhibited a clear vitreous humor in a choroid cup. No trace of eyes is to be detected in the terminal segment of the body, such as exist in *Fabricia*.

In several instances in which I have extracted *Manayunkia* from its tube a number of young ones, about half a dozen, have been liberated, from which it appears that the eggs are laid within the tube, there hatched, and the young then retained under the care of the parent until sufficiently developed to be able to care for themselves.

Figures 8-13, plate IX, represent an ovum and a series of young in different stages of development, which were obtained, together with others in the same condition, from three tubes.

The ovum, Fig. 8, about 0.2 mm. long, obtained with several similar ones from a tube, exhibits a central mass of large yolk cells enclosed by a layer of smaller ones. Fig. 9 represents an embryo which accompanied the former. It was motionless and devoid of cilia. The yolk cells appear to have been resolved into a stomachial cavity. The embryo was about the same size as the ovum. Fig. 10 represents a more advanced embryo from the same tube. It measures 0.265 mm. in length. The intestine indicates a division into eight segments. Fig. 11 is a more advanced stage of development of the worm from another tube. It measured one-third of a millimeter in length. The body wall and intestine are quite distinct, the latter exhibiting eight segments. The tentacular lobes have

commenced development. Fig. 12 represents an individual further developed, from the same tube as the former. It measured half a millimeter long. The body is distinctly divided into nine segments, of which eight bear a pair of setæ on each side. The tentacular lobes exhibit each the rudiments of four tentacles. Eyes also have made their appearance. Fig. 13 represents a young worm from another tube, the only one accompanying its parent. It measured 0.72 mm. long. The body is divided into the same number of segments as in the former. The tentacular lobes have developed each four tentacles, with the rudiment of a fifth. Podal hooks could be detected in none of the segments except the last, in which there were three comb-hooks on each side. Another young individual, observed from another tube, about the same size as the preceding, had five tentacles on each side, but was otherwise exactly similar. Another individual, three-fourths of a millimeter long, with five tentacles on each side, had one more setigerous segment than in the others.

The species of *Fabricia* to which I referred in the beginning of the present communication, and which I examined with particular interest on account of the near relationship of *Manayunkia* to it, is the same as that described by Prof. Verrill as being common from New Haven to Vineyard Sound and at Casco Bay. (See Report on the Sea Fisheries of New England, Washington, 1873, p. 619.) I first noticed the worm at Newport, Rhode Island, in 1858, and found it abundantly at Bass Rocks, Gloucester, Mass., in 1882. It occurred on rocks between tides, under a luxuriant growth of *Fucus vesiculosus*, with its tubes projecting from among the mud and sand, firmly fixed together with multitudes of little mussels about the roots of the seaweed.

The worm is three or four millimeters long and of a yellowish or yellowish brown hue, with more or less reddish. The body is compressed cylindrical and slightly tapering behind, and is divided into twelve segments, including the head. This is prolonged dorsally in a half elliptical process or upper lip. The vertex supports on each side a trifurcate lophophore, each fork of which is provided with a double row of narrow cylindrical tentacles invested with cilia.

The segments succeeding the head are furnished with lateral fascicles of podal setæ, and, except the first one, are provided with fascicles of podal hooks, all of which have the same general arrangement and form as those described in *Manayunkia*. The fascicles of podal setæ, from the first to the eighth segments, usually contain six or seven setæ; those of the ninth and tenth segments, three or

four setæ, and those of the eleventh segment two or three setæ. The longer setæ, Figs. 14 and 15, resemble those of *Manayunkia*, consisting of a straight rod, with a feather-like vane ending in a long point and bent at an obtuse angle from the rod. The stouter setæ, Fig. 16, have the same form, but differ in the variably much shorter proportion of the vane. The setæ range from 0.12 to 0.25 mm. long.

The first setigerous segment possesses no podal hooks, as in the case of *Manayunkia*. The fascicles in the succeeding segments to the fourth contain each eight or nine hooks, and those following to the eighth, inclusive, six or seven hooks. The hooks of the remaining three segments, as in *Manayunkia*, are very different from those of the anterior segments, and are arranged in close transverse semicircular rows of from 20 to 28 in each row.

The anterior podal hooks consist of a curved handle ending in a short robust hook, like those of *Manayunkia*, but differing in the hooks, being furcate, or even divided three or four times on the dorsum, as represented in Figs. 17 and 18. These podal hooks usually measure about 0.08 mm. long.

The posterior podal hooks resemble the corresponding ones of *Manayunkia*, as represented in Fig. 19. They measure from 0.035 to 0.04 mm. long.

The intestinal canal of *Fabricia* has the same simple character as that described in *Manayunkia*. The mouth has a pair of palp-like appendages, situated between the lophophores. The vascular system appears to exhibit the same arrangement as in *Manayunkia*, but the blood is of a red color.

Fabricia is remarkable for being furnished with a pair of eyes to the terminal segment of the body as well as to the head. The eyes are of simple character, but equally well developed at both extremities of the body. They consist of a black pigment cup, including a spheroidal vitreous body. In several instances I observed a curious variation of the eyes in different individuals and on the different sides of the same individuals. Fig. 20 represents the usual form of the cephalic eye. Figs. 21 and 22 represent the two eyes of the same individual, the right eye apparently double. Fig. 23 represents another double eye, but with the lens directed backward. Fig. 24 represents a caudal eye.

The tube of *Fabricia* is composed of exceedingly fine particles of quartzose sand and indefinite particles of mud.

I observed no specimens of this genus exhibiting the reproductive organs in the condition usual in mature ones of *Manayunkia*.

In several instances I observed a few free eggs and young worms of 0.12 mm. in length within tubes in company with the parent, but did not have the opportunity of investigating them.

Manayunkia mainly differs from *Fabricia* in having a pair of simple or undivided tentacular lophophores instead of having them trilobate; in the possession of an inner pair of larger tentacles, which receive a continuation of the main trunks of the vascular system, and in having no eyes to the terminal segment of the body.

EXPLANATION OF THE FIGURES OF PLATE IX.

Fig. 1. *Manayunkia speciosa*. Magnified about 50 diameters. The worm in the ordinary condition of extension, with its tentacles spread.

Fig. 2. A stock of five tubes. Magnified about 4 diameters.

[December, 1883. Nos. 514 and 518. See Bibliography.]

A Fungus infesting Flies.—Prof. Leidy directed attention to a vial filled with flies adherent to fragments of leaves. He stated that on the first of August, the last summer, he had noticed that from the swarm of flies attracted by the ripe fruit of a black mulberry, *Morus nigra*, many settled on the under sides of the leaves, and there became fixed and died from the invasion of a fungus, in the same manner as the house-fly often becomes attached to walls

and window panes in the autumn through the agency of the fungus known as the *Sporondonema*. The infested flies on the mulberry tree were so numerous that perhaps a fourth of the foliage of the lower boughs had from one to half a dozen of the flies adherent to each leaf. The fly, though a familiar one, is unknown by name to him. It resembles the house-fly, but is larger and has a black abdomen with lateral whitish spots. The fungus of a fuscosus hue is especially evident in the extended intervals of the segments of the abdomen along the sides of the thorax and at the neck. Though extending to and attaching the flies to the leaves, the specimens do not exhibit the zone of spores on the leaf as commonly seen in those of infested house-flies. Microscopic examination exhibited a similar structure of the fungus to that of the *Sporondonema* or *Empusa musca*. It mainly consists of translucent, cylindrical, straight, or somewhat tortuous rods or tubes of variable length with rounded ends and containing homogeneous liquid with rows of oil-like globules. Mingled with the tubes are numerous oval, ovoid, and pyriform spore-like bodies, usually each with two oil-like globules. The spore-like bodies measure 0.028 to 0.036 mm. long by 0.016 mm. thick. The longer tubes measure usually up to 0.16 mm. long by 0.012 mm. thick.

[January, 1884. Nos. 519, 522. See Bibliography.]

Ant infected with a Fungus.—Prof. Leidy exhibited an ant, *Camponotus pennsylvanicus*, which was rigid, with limbs and antennæ extended, as in life, in which condition it was found under the bark of a decaying tree. It was infected with a fungus which spread through every part of the body.

Distoma and Filariae.—Prof. Leidy directed attention to some parasitic worms presented this evening. Some of these were supposed to be leeches from the mouth of the alligator. Herodotus states that the crocodile of the Nile has the inside of its mouth always beset with leeches. The existence of the leech has been confirmed, and is known as the *Bdella nilotica*. The present specimens, however, do not belong to a leech, but pertain to a species of *Distoma*, apparently not previously described. It may be named and be distinguished by the characters as follows:

Distoma oricola.—Body elongated elliptical, moderately wider and thicker posteriorly, and ending in a blunt, angular extremity, convex dorsally and flat ventrally, unarmed, smooth or minutely wrinkled transversely. Mouth subterminal, and enclosed with a reniform lip succeeded by a linear annulus. Acetabulum large, globular, in-

cluded at the anterior fourth of the body, and opening ventrally by a conspicuous central aperture. Generative orifice ventral at the posterior fourth of the body. Length 15 to 20 mm.; breadth 3 mm. Eight specimens obtained from the mouth of the alligator, *A. mississippiensis*, in Florida, by Mr. Stuart Wood.

Accompanying the specimens is a fragment of the tongue marked with circular scars, apparently due to the worms. The alcoholic specimens in their present condition are incurved, with the lateral margins inverted, and the included acetabulum produces a conspicuous dorsal eminence.

Of several Filariae exhibited, two, a female and a male, pertain to the species *Filaria horrida*, Diesing. The former is 28 inches long, the latter 11 inches. They were obtained by Dr. Henry C. Chapman from the thorax of the American ostrich, *Rhea americana*. The other specimens were obtained by Mr. P. L. Jouy from the abdomen of *Strix brachyotus*. They consist of four females from 12 to 14 inches long and a half a line thick, and two males $2\frac{1}{2}$ inches long and one-fourth of a line thick. They are thicker anteriorly with the head end obtusely rounded, and with the mouth minute and bounded by a minute pair of conical lips. The tail end of the female is straight and blunt; that of the male is more tapering, and is included in an elliptical alary appendage, supported on each side by a row of five curving ribs. A pair of similar, but shorter and straight papillæ, is situated near the anal aperture, and a pair of pointed processes diverge from the end of the tail into the alary expanse.

Two species of *Filaria* have been previously observed in *Strix brachyotus*, *F. attenuata* Rud., and *F. foveata* Schn., to neither of which the specimens under examination appear to belong. These, however, so closely accord with the descriptions of *F. labiata* Creplin, from the black stork, *Ciconia nigra*, that, notwithstanding the remote relationship in the host, the speaker believed them to belong to that species. In the construction of the caudal extremity of the male they closely approximate the condition of *F. labiata* and *F. horrida*, as represented in the figures of Schneider (Monographic der Nematoden), while they are widely different from that of *F. attenuata* and *F. foveata*, as represented in similar figures of the same work.

[May, 1884. No. 526 See Bibliography.]

A Rare Human Tapeworm.—Dr. Leidy directed attention to some little tapeworms which had recently been submitted to his exam-

ination by Prof. William Pepper. They were expelled, by the use of santonin, from a child of three years. The specimens, consisting of a dozen fragments, appear to be portions of three worms, which reached a length of from twelve to fifteen inches or more. Unfortunately the head is lost. The joints or proglottides are more than several times the breadth of the length. In a specimen of thirteen inches, comprising nearly a complete worm, the joints of the anterior attenuated extremity are about one-fifth of a millimeter long by nearly two-thirds of a millimeter wide, while the posterior joints are half a millimeter long and two and a quarter millimeters wide. Ripe joints at the posterior part of the body are pale brown, the color being due to the eggs. These occupy a simple uterus defined by the walls of the joints, and not divided into pouches diverging laterally from the main stem as is usual in most taeniae. A singular feature of the worm is the interruption of the series of ripe joints, here and there, by one or more completely sterile ones. The generative apertures open in the usual way on the lateral margin of one side. The mature eggs are spherical, measure 0.072 mm. diameter, and contain, fully developed, six hooked embryos.

While differing greatly from the ordinary tapeworms infesting man, they approximate nearly the description of *Tænia flavopunctata*, and probably pertain to this species. This has been but once previously observed, and was described in 1858 by Dr. Weinland (An Essay on Tapeworms of Man) from specimens in the Museum of the Medical Improvement Society of Boston. These were also discharged by a child. The worm was estimated to be from eight to twelve inches. The joints were marked by a yellow spot, from which the species was named. The eggs measured from 0.054 to 0.06 mm.

Our specimens indicate a worm almost the same size as the *T. flavopunctata*, but the joints are shorter and wider, and exhibit no yellow spot, and the eggs are larger. In other characters the worms sufficiently accord to render it probable that they may pertain to the same species. It is probable that the worm is more common than would be supposed from the instances of its observation, and has perhaps escaped notice from its small size and from the general ignorance of the distinction, not only of this, but of the ordinary species of tapeworms.

A more complete account of the subject of this communication will shortly appear in the American Journal of Medical Sciences.

[May, 1884. No. 527. See Bibliography.]

Pentastomum proboscidcum.—Prof. Leidy exhibited specimens of this parasite, presented to him by Mr. Norman Spang, of Etma, Pa., who recently obtained them in Florida from the lung of a large rattlesnake, *Crotalus adamanteus*. They are cylindrical incurved, annulated, largest and rounded at the head, tapering behind, and becoming again larger and rounded at the end, and terminating ventrally in a short conical point. There are six of them, with the following measurements: 9 lines long by $1\frac{1}{2}$ lines at the head; 13 lines by $1\frac{1}{2}$ lines; 24 by $2\frac{1}{2}$; 28 by $2\frac{1}{2}$; 30 by 3, and 31 by 3. The species was first found by Humboldt in *Crotalus horridus*. It is common in the Boa constrictor, in which Prof. Leidy had also observed it several times. It has likewise been found in a number of other serpents. Other species occur in different mammals, including man, reptiles, and fishes. These singular parasites are regarded as the most degraded form of arachnida, in the mature stage being reduced to a worm-like, limbless body.

[October, 1884. No. 528. See Bibliography.]

Organisms in Ice.—Prof. Leidy stated that a member had placed in his hands for examination a vial of water obtained from melting ice which is used for cooling drinking water. From time to time, among some sediment taken from a water-cooler, the gentleman had observed what he supposed to be living worms, which he suspected were introduced with the water into the cooler and not with the ice. Upon melting some of the ice alone the worms were still observed, and the water submitted for examination was some that was thus obtained. Prof. Leidy was surprised to find a number of worms among some flocculent sediment, mainly consisting of vegetal hairs and other débris. Besides the worms, there were also immature Anguillulas and a number of *Rotifer vulgaris*, all living. It would appear that these animals had all been contained in the ice and had been liberated on melting. It was an unexpected source of contamination of our drinking water that Prof. Leidy had previously supposed to be very improbable. The little worms he was not familiar with.

They belong to the family of Lumbricidae and probably may be an undescribed species of *Lumbriculus*. They are white, or colorless, from 4 to 6 millimeters long by a third of a millimeter in thickness. The body is divided into thirty segments, bearing podal spines, which form four rows, with three in each fasciculus, and

divergent. The spines are curved at the root, pointed at the free end, and measure 0.05 to 0.06 mm. long. The upper lip is blunt conical; the terminal segment truncate. There appears to be no distinct girdle, but the third, fourth, and fifth segments contain capsuligenous glands and other organs pertaining to the sexual apparatus.

Several dead worms swarmed in the interior, with large ovate, beaked, ciliated infusorians measuring from 0.05 to 0.06 mm. long by 0.04 to 0.048 mm. broad.

[January, 1885. No. 530. See Bibliography.]

On some Parasitic Worms of Birds.—Prof. Leidy stated that Dr. B. H. Warren, of Westchester, much interested in ornithological pursuits, had submitted to his examination a number of parasitic worms obtained in the preparation of specimens. Recently he had sent to him the carcass of a Snow Bird, *Junco hyemalis*, in which he reported a multitude of worms filling the thoracico-abdominal cavity and extending into the neck and beneath the skin of the breast and abdomen. From the carcass seventy-two worms were obtained, of which two-thirds were females, ranging from 90 to 120 mm. in length; the rest males, ranging from 40 to 55 mm. From the abdomen of another bird Dr. Warren obtained five worms, three females from 55 to 90 mm. and two males 40 and 55 mm. In twenty-two birds examined by Dr. Warren the parasites were found only in the two indicated. The worms appear to be the *Filaria obtusa*, Rudolphi, which infests the *Hirundo rustica* and other species of European Swallows. The worms of the Snow Bird reach double the length of those of the Swallows, but in other characters agree with the descriptions of *F. obtusa*, as given by Diesing and Dujardin, and also with the figures given by the latter (*Hist. Helminthes*, pl. iii), except that it is uncertain as to the existence in our specimens of the buccal armature represented by Dujardin. The worms are translucent white, with a chocolate-brown intestine and white uteri and testes. The caudal extremity is obtuse without appendages, and in the male possesses two spicules, of which the longer curved one is 1.125 mm. long and the shorter twisted one 0.5 mm. long. The ova, containing developed embryos, are 0.045 mm. long and 0.032 mm. broad.

Six other specimens, apparently also pertaining to *Filaria obtusa*, Dr. Warren obtained from the abdominal cavity, partly imbedded in the wall, of a Meadow Lark, *Sturnella magna*. Two are females

130 and 140 mm. long by 0.625 mm. thick and four are males from 50 to 60 mm. long by 0.5 mm. thick.

Six specimens of another *Filaria* were obtained from the abdomen of a female Kingfisher, *Ceryle alcyon*. The species appears to be the *Filaria physalura* of Bremer, described from specimens obtained from several species of Brazilian Kingfishers. Five of the worms are females ranging from one foot to one foot and a half in length and from one to one and a half millimeters in thickness. The head is obtuse and the body gradually tapers to the tail. The mouth is bounded by a pair of small conical papillæ. The five females measure, respectively, 12, 13, 14, 17, and 18 inches. A single male is 35 mm. long by 0.625 mm. thick. The tail is incurved, ends in a minute blunt cone, and is bialate, with the alæ short and quinquecostate. The length of the alated portion is 0.35 mm. The spicule, partially exserted, is recurved. The specimens, when alive, were pink in color and exhibited a slender chocolate-brown intestine, with large tortuous white uteri.

From the thoracic cavity of a Gray Snipe, *Gallinago Wilsonii*, Dr. Warren obtained five Flukes 18 mm. long by 4 mm. broad. These appear to be *Monostomum mutabile*.

From a whippoorwill, *Antrostomus vociferus*, Dr. Warren obtained four worms, two females of 18 mm. and two males of 12 mm., which appear to be *Ascaris subulata*.

From the Pileated Woodpecker, *Hylotomus pileatus*, Dr. Warren obtained ten worms which appear to pertain to the *Spiroptera quadriloba* Rudolphi, the female of which was originally described from specimens found in the Green Woodpecker, *Picus viridis*. The specimens are reported as having been found in the abdominal cavity. Six are females from 9 to 12 mm. long by 0.5 mm. thick and four males 7 and 8 mm. long by 0.375 mm. thick. Body white, nearly equally attenuated toward both ends; transversely wrinkled and anteriorly minutely, regularly, and sharply annulated; mouth quadrilobate. Tail of female conical subacute; tail of male bialate, sexcostate, end acute; spicules two, the longest 1.5 mm. long, the shortest 0.5 mm. long.

[**May, 1885. No 533. See Bibliography.]**

Bothriocephalus in a Trout.—Prof. Leidy remarked that through Dr. B. H. Warren he had recently received from the Smithsonian Institution several vials with tapeworms, obtained by Mr. L. M. Turner from a trout, *Salvelinus* — ?, at Ft. Chimo, Ungava. One of the vials contained eight worms, ranging from 3 to 8 inches long

together with fragments of others, and was labeled "Passed from a Trout caught in the river August 14, 1882." The worms belong to a species of *Bothriocephalus* or *Dibothrium*, apparently different from either the *D. infundibuliforme* or *D. proboscideum*, found in *Salmo salvelinus*, *S. salar*, *S. trutta*, and other fishes of the kind. The specimens are all mature, the segments from near the head throughout being distended with brownish eggs. The characters of the worm are as follows: Body linear, bandlike, widest just behind the head and gradually narrowing to the posterior extremity, thickened along the middle and to a less degree along the lateral borders, which are narrowly obtuse at the free edge, apparently continuous, but irregularly crenulate; the broad surfaces transversely wrinkled, with the lateral borders defined from the middle by longitudinal striae; anterior extremity wider and transversely convex; posterior extremity obtusely rounded. Head small, oval, equitant across the anterior border of the body, with an oval bothria fore and aft, directed obliquely from the broad surfaces of the body. No distinct neck. Segments of the body commencing immediately after the head, wider than long, indistinctly defined at the lateral margins and most marked transversely along the middle of the body, becoming narrower and slightly longer at the posterior part of the latter, fertile throughout and furnished on one side of the body, in the median line, with a prominent penal papilla and just behind with a genital pore. Animal whitish, with a median chain of brownish spots, due to the ova-distended uterus.

In a specimen of eight inches in length the anterior extremity of the body is 3 mm. wide, at the middle 2 mm., and at the posterior extremity 1.5 mm. The head measures 0.16 mm. transversely and 0.18 mm. deep or long on the broad aspect of the worm. The segments generally measure about 0.625 mm. long. The ova are brownish, oval, and 0.04 mm. long by 0.024 broad.

The second vial contains a single worm and is labeled "Taken from the intestine of a Trout Aug. 29, 1882." This worm I suspect to represent an immature stage of the former. It is 30 mm. long and in shape resembles the fluke-worm or a leech. It is elongated elliptical, flat, widest in front, with the lateral margins apparently entire, the broad surfaces transversely striated and longitudinally divided into three bands, with the median band indistinctly divided into segments, on one surface in the median line provided each with a minute pore. Head oval, situated fore and aft across the anterior transversely convex border of the body, with a minute oval bothria fore and aft. Caudal extremity narrowest transversely

convex at the end and emarginate or with a pore. Breadth at fore part 3 mm., at back part 2 mm. The species may be named *Bothriocephalus (Dibothrium) cestus*.

[December, 1885. No. 534. See Bibliography.]

Worms in Ice.—Prof. Leidy referred to a former communication on the occurrence of organisms in ice (see Proc. 1884, 260), and stated that Dr. C. S. Thornton, of Moorestown, N. J., a couple of weeks since, had submitted to him for examination a bottle of water from melted ice, such as was habitually used in his family, and in which he said he had observed living worms. A number of these proved to be present in the specimen, but were all dead. Having expressed a desire to confirm the statement that the worms were observed alive in fresh ice-water, Dr. Thornton last week had obligingly sent him a basket of the ice. This was part of the provision made nearly a year ago from the vicinity of Moorestown. The ice was full of air bubbles and water drops. On being melted a number of the worms were liberated and proved to be in a living and quite active condition. It is probable that while imprisoned in the ice they may not have been frozen, but perhaps remained alive in a torpid condition in water drops. It is a remarkable fact that these animals should remain so long alive in ice, and yet die so readily in the melted water subsequently. The worms are of the same species noticed in the ice-water of the first communication, and which was derived from similar ice procured from a mill-pond in Delaware Co., Pa. These facts would indicate that it is desirable to avoid the spongy ice from stagnant waters as being liable to retain organisms which would be detrimental to us. In the clear ice, such as is served in Philadelphia, no living organisms are detected. The little worms of the ice appear to be an undescribed species, and may therefore be characterized as follows:

Lumbricus glacialis.—Worm from four to six lines long, translucent, white, cylindrical, anteriorly acute, tapering most behind and obtuse, of from 35 to 50 segments; oral segment with a blunt conical upper lip, unarmed and eyeless; succeeding segments with four rows of podal-spines, in fascicles of three; spines pointed at the free end and hooked at the attached end, nearly straight or slightly sigmoid; generative organs occupying the interval of the third and seventh spine bearing segments. Thickness of worm 0.15 to 0.25 mm.; podal spines 0.3 to 0.375 mm. long.

The length given in the former notice should be in lines instead of millimeters.

[March, 1886. No. 539. See Bibliography.]

On Amia and its probable Taenia.—Prof. Leidy stated that in our market on Saturday last three Mud-fishes, *Amia calva*, had been given to him. They came in a barrel of shad from North Carolina. One was a female about two feet long, the others male, of which the smallest was eight inches. Protruding from the vent of the latter was a little tapeworm, which, on disturbance, retreated into the rectum. Three other worms of the same kind were found in the mouth, but none in the intestine of this or the other fishes. The worms accorded with the description of the *Taenia filicolis*, infesting Sticklebacks, *Gasterosteus*, and is probably the same species. They range from $1\frac{1}{2}$ to 3 inches long, gradually widening from the delicate thread-like neck to the posterior rounded extremity, where they measure from 1 to 1.5 mm. wide. The head is spheroidal, variably broader or longer, and about 0.625 mm., with the summit slightly prominent and unarmed and with four hemispherical, lateral bothria 0.25 mm. in diameter. Neck variable, when extended long and narrow and usually about half the width of the head. Anterior segments, transversely linear, about an eighth the length of the breadth, gradually becoming inverted saucer-shaped or scutellate, and about one-fourth the length of the breadth. Posterior segments more quadrate, slightly widening behind, about 0.75 mm. long and from 1 to 1.5 mm. broad; last segment longest and rounded. Genital apertures marginal.

[August, 1886. No. 541. See Bibliography.]

NOTICES OF NEMATOID WORMS.

Filaria scapiceps.—Body cylindrical, nearly equally tapering at the ends. Cephalic extremity abruptly narrowing, cylindric, rounded at the summit and smooth. Mouth a terminal pore without labia, papillæ, or inner armature. Caudal extremity of female nearly straight, conical, obtusely rounded, smooth, without appendages; of the male curved, conical, obtusely rounded alate and papillate; alæ half oval; papillæ five pair, pyriform, successively decreasing to the last at the end of the tail. Genital aperture opening between the ante- and penultimate papillæ; penal spicules short, curved.

Female 25 to 30 mm. long; 0.75 wide at middle; head 0.175 wide.
Male 12 mm. long; 0.375 wide at middle.

Eight females and five males were obtained from beneath the skin of the hind foot of a rabbit, *Lepus sylvaticus*. (Drawing.)

Filaria obtunsa.—Body cylindrical, nearly uniform, head conical, obtusely rounded, or rounded truncate, smooth; mouth a minute central pore, devoid of lips, papillæ, or internal armature; caudal end of female straight, conical, obtusely rounded, devoid of papillæ; of male abruptly narrowed, a length about equal to the breadth of the body, nipple-shaped, obtusely rounded and devoid of papillæ. Female genital aperture near the head end. Male aperture terminal; penis of a longer curved spicule and a spiral one of half the length.

Female 4 inches or more long, 0.625 mm. wide. Male 2 inches long, 0.5 mm. wide. Abundant in the visceral cavity of the snow bird, *Junco hyemalis* = *F. obtusa*, Leidy, P. A. N. S., 1885, 10. In the meadow lark, *Sturnella magna* = *F. obtusa*, ibidem, Chester Co., Pa.

Many specimens from the visceral cavity of the meadow lark in the collection of the Army Medical Museum, Washington. Female from $4\frac{1}{2}$ to $7\frac{1}{2}$ inches long, mostly 6 inches; width 0.625 mm. Male $2\frac{1}{2}$ to $3\frac{1}{2}$ inches.

Four females and a male from the crow black bird, *Quiscalus purpureus*. They are proportionately more robust than the preceding. Female 4 inches long and 0.875 wide. Male $1\frac{1}{4}$ inches long and 0.5 mm. wide. Florida. Dr. B. H. Warren.

I at first viewed this species as the *Filaria obtusa*, Rudolphi (Diesing, Syst. Hel., ii, 267). The caudal extremity of the male, with its penal armature, accords with Dujardin's figure of that species (Helmintes, Pt. iii, fig. j, 2). In *F. obtunsa* I can detect no buccal armature such as exists in *F. obtusa*, according to Dujardin; and later, Molin (Versuch einer Monographie der Filarien, Sitzungsbl. Wien. Akad. Wis., 1858, 397).

Filaria cirrura.—Body cylindrical, nearly equal, cephalic end conical, rounded truncate, smooth; mouth a minute funnel-like orifice without papillæ or interior armature; caudal end of female slightly curved or nearly straight, conical, obtusely rounded, without appendages; of male closely rolled inward, conical, blunt, without alæ or papillæ; penal spiculæ strongly curved, with the points projecting from the prominent genital aperture situated above the tail end.

Length of female 16 mm., breadth 0.5 mm. Length of male 10 mm., breadth 0.375 mm.

Four females and two males from the orbit of the jackdaw, *Quiscalus major*. Florida. Dr. B. H. Warren.

Filaria nodulosa, Rudolphi. Diesing, Syst. Hel., ii, 274. Body cylindrical, nearly uniform, slightly more narrowed behind. Head conical, obtusely rounded, with a circle of minute tubercles. Caudal extremity of the female straight, conical, obtuse; of the male

slightly curved, obtuse. Genital aperture a little in advance of the tail end. Penial spicules short, curved.

Females 3 inches long, 1 mm. wide. Male $1\frac{1}{4}$ inches long, 0.5 mm. wide.

One of each sex from beneath the skin of the head and neck of a shrike, *Collurio ludovicianus*. Florida. Dr. B. H. Warren.

Filaria stigmatura.—Body filiform, nearly uniform cylindrical, but attenuated at the cephalic extremity. Head rounded truncate, smooth. Mouth large, bordered by two or three? minute, conical papillæ, unarmed within. Integument smooth throughout, not annulate. Female: Caudal extremity straight, smooth; tail straight or slightly bent back from the distinct anal aperture, conical, blunt. Male: Caudal extremity spirally enrolled two or three times, furnished with narrow band-like granular alæ sustained by twelve pairs of ribs or cylindroid papillæ, of which seven pair are preanal; tail curved conical, subacute; penial spicules, one four times the length of the other.

Length of female 40 to 55 mm.; breadth 0.5 mm.; tail 0.3 mm. long. Length of male 24 to 30 mm.; breadth 0.375 mm.; tail 0.25 mm. from genital aperture; long penial spicule 0.88 mm., short one 0.2 mm. Pharynx cylindrical, 0.25 mm. long; oesophagus cylindrical, slightly expanded at lower end, 3 mm. long; intestine nearly same diameter. Eggs thick-shelled, oval, 0.04 long, 0.024 broad.

A multitude of individuals obtained from the swimming bladder of the lake trout, *Salvelinus namaycush*. Lake Superior. Dr. James H. Bissell.

The species bears considerable resemblance to *Ancyracanthus cystidicola* (Rud, Schneider, Mon. d. Nematoden, 105), from a like position of *Salmo furio* of Europe, but it possesses distinct characters, even generic. It also resembles *Filaria dentiulata* (Ib., 102), but is devoid of the tegumentary spines and other characteristic marks of that species.

Filaria helicina, Molin. Sitzungsb. Wien. Akad. Wiss., 1858, xxviii, 391.

Filaria anhingæ, Wyman. Proc. Boston Soc. Nat. Hist., 1868, 100.

Enstrongylus, Packard. Hayden's Rep. U. S. Geol. Surv., 1873, 735.

Filaria Wymani, Leidy. Proc. A. N. S., 1882, 109.

Numerous additional specimens from the brain of a dozen individuals of *Plotus anhinga*. Florida. Dr. B. H. Warren.

Trichosomum tenuissimum. Diesing, Syst. Helm., ii, 256. Body cylindrical, obtuse at both ends, viviparous. Four females, 7 lines long by 0.25 mm. thick. Intestine of the dove, *Zenaidura carolinensis*. From two birds. Florida. Dr. B. H. Warren.

? *Monopetalonema eremita*.—Body cylindrical, slightly narrowest anteriorly. Head with an annular expansion of the integument, which is more dilated below. Mouth with a pair of half-conical lips, divided into four papillæ at the apex. Tail short, straight, conical, obtuse.

A single female 19 lines long and nearly 1 line thick at the middle. Obtained by Dr. J. Van A. Carter from the masseter muscle of a badger, *Meles labradorica*, at Ft. Bridger, Wyoming.

The head and mouth have the characters of *Physaloptera*. Two apertures are visible in advance of the end of the tail, one at the distance of 0.25 mm., the other 0.625 mm.

Ascaris simplex, Rudolphi. Diesing, Syst. Hel., ii, 155.

A large quantity from the stomach of a dolphin, *Lagenorhynchus*? Pacific Ocean. Dr. Wm. H. Jones, U. S. N.

Ascaris compar, Schrank. Diesing, Syst. Hel., ii, 170.

One male 1 $\frac{3}{4}$ inches long. Intestine of the quail, *Ortyx virginianus*. Florida. Dr. B. H. Warren.

Ascaris vesicularis, Frolich. Diesing, Syst. Hel., ii, 148.

Two females and two males. Intestine of the quail, *Ortyx virginianus*. Florida. Dr. B. H. Warren.

Ascaris depressa, Rudolphi. Diesing, Syst. Hel., ii, 156. Intestine of *Strix niva*, Leidy, Pr. A. N. S., 1858, 112.

Two females 2 $\frac{1}{2}$ inches by 3 mm. Intestine of *Strix brachyotus*. Florida. One female 1 $\frac{3}{4}$ inches. *Bubo virginianus*. Chester Co., Pa. Dr. B. H. Warren.

Ascaris ensicandata, Rudolphi. Diesing, Syst. Hel., ii, 184. Labia large and prominent; apex of tail defined as a short ensiform appendage. Five females to 3 inches long by 1 mm. broad. Ejected from the mouth of a mocking bird, *Mimus polyglottus*. Jacob Geismer.

Ascaris microcephala, Rudolphi. Diesing, Syst. Hel., ii, 155.

Numerous specimens from the stomach of the night heron, *Nyctardea grisea*. Chester Co., Pa. G. W. Roberts, through Dr. B. H. Warren. Specimens from *Ardea herodias*, *Hydranassa tricolor*, and *Botaurus mugitans*. Florida. Dr. Warren.

Ascaris spiculigera, Rudolphi. Diesing, Syst. Hel., ii, 157.

From *Graculus dilophus*, *Plotus anhinga*, *Pelicanus trachyrhynchus*, and *P. fuscus*. Leidy, Proc. Acad. Nat. Sci., 1858, 110; 1882, 109.

Numerous additional specimens from the former two birds. Florida. Dr. B. H. Warren.

Ascaris tenuicollis. Rudolphi, Syst. Hel., ii, 160.

Numerous specimens, all females, up to $1\frac{1}{2}$ inches long and 2 mm. thick. From the *Alligator mississippiensis*.

Ascaris anoura, Dujardin. Diesing, Syst. Hel., ii, 161.

Numerous females 3 and 4 inches long to 2 mm. thick. These were all suspended in the stomach, through double apertures of the mucous membrane, and thus tightly retained in position. From a snake which, from the description, is supposed to be the milk-snake, *Ophibolus*. Obtained by Dr. James Bissell in the vicinity of Harrisburg, Pa.

Ascaris penita.—Body cylindrical, tapering at the extremities and most attenuated in front. Mouth trilabiate. Tail of female long, straight, conical, subulate; of male of same form strongly curved, with the point brought near the genital aperture; provided at the posterior third with four pair of papillæ. Penal spiculae remarkably robust.

Length of female 5 to 7 lines by $\frac{1}{2}$ line in width; of male to 5 lines by 0.375 mm. in width. Numerous specimens from the intestine of *Trachemys scabra*. Generative aperture of the female at the posterior third of the body. Oesophagus long, cylindrical, followed by an oval or spherical gizzard. Commencement of intestine dilated. Oesophagus 1.75 mm. long by 0.125 wide. Gizzard about 0.25. Tail of female 1.25 mm. long. Breadth of penal spicules 0.08 mm.

Physaloptera torquata.—Body cylindrical, most attenuated anteriorly. Head with a conspicuous narrow annular fold or collar. Mouth bilabiate. Labia half conical, with a pair of lateral papillæ, and the apex provided with a group of four, of which one is external to the others. Tail short, conical, obtuse, recurved from the anal aperture.

Numerous specimens, all females, from 3 to 6 lines wide and 1-4th of a line thick. Worms all more or less spirally coiled. From the stomach of the badger, *Meles labradorica*.

Physaloptera turgida, Rudolphi. Diesing, Syst. Hel., ii, 233; Leidy, Pr. A. N. S., 1856, 53.

From the stomach of the opossum, *Didelphis virginiana*. Collection of the Army Medical Museum, Washington; also received from Dr. Benjamin Sharp.

Physaloptera abbreviata, Rudolphi. Diesing, Syst. Hel., ii, 235. Numerous females from 3 to 8 lines and three males about 2 lines.

From the visceral cavity of *Phrynosoma regale*. Collection of the Army Medical Museum, Washington. Nose, mouth, and throat of *Phrynosoma hernandezii*: Sonora, Mexico. Dr. T. H. Streets.

Hedruris androphora, Nitzsch. Diesing, Syst. Hel., ii, 205.

Symplecta pendula, Leidy. Pr. A. N. S., 1851, 240; 1856,

52. Diesing, Sitzungsb. Wien. Akad. Wis., xlvi, 1861, 647.

Stomach of *Nanemys guttatus*.

Cucullanus roseus, Leidy. Pr. A. N. S., 1851, 155; 1856, 54.

Intestine of *Manouria fusca*, Java.

Tropidocerca certa.

? *Filaria dubia*, Leidy. Pr. A. N. S., 1856, 55.

Female subglobular, broader than long, divided into zones: tail abruptly projecting and conical. Male of the ordinary nematoid shape, cylindrical, most attenuated in front. Mouth trilabiate. Caudal extremity strongly rolled inwardly, sigmoid at the end, which is conical, recurved from the genital aperture, mucronate and alate: alae half oval, narrowing to the end of the micro, which is truncate. Female 7 mm. long by 7 and 8 mm. broad. Male 12 to 18 mm. long and 0.375 to 0.5 wide. The specimens of this curious parasite were contained in two spherical cysts in the wall of the stomach of the albatross, *Diomedea exulans*. Each cyst contained a corpulent female with severally four and five males. Obtained by Dr. W. S. W. Rusenberger.

[January, 1887. No. 543. See Bibliography.]

NOTICE OF SOME PARASITIC WORMS.

Filaria megacantha.—Body straight, nearly uniform cylindrical, slightly narrowed posteriorly, obtuse at the ends, milk-white in color; head rounded; mouth bounded by a pair of prominent papillate lips. Female caudal extremity straight, obtusely rounded, smooth, without anal aperture. Male: caudal extremity conical, obtuse, bialate; alae narrow, united around the end of the tail, together forming a shallow pouch, with a row on each side of six rib-like papillæ, of which four are in advance and two behind the genital aperture. A long, curved and partially exserted penile spiculum and a nearly straight short one.

Eight females, 35 to 60 mm. long; cephalic extremity a short distance back, 0.75 wide; body at middle, 0.625; near the tail end the same width. Seven males, 20 to 25 mm. long; cephalic extremity, 0.375 wide; body at middle, 0.5; near tail end, 0.25 wide.

Large penile spiculum, 2.5 to 3 mm. long; shorter one 0.18 to 0.22 mm.; caudal bursa, 0.28 long; width of aede, 0.036 mm. (Drawing.)

From the subcutaneous connective tissue of the neck and mandible of the Short-eared Owl, *Asio occipitrinus* (*Strix brachyotus*).

This appears to be a much smaller and different species from the *Filaria attenuata* Rud., found in the same bird and others of the order in Europe. Dujardin (Helminthes, 51) gives as the size of the latter 250 to 308 mm. for the female, and 136 to 148 mm. for the male, with 1 mm. for the longer penile speculum. Schneider gives (Monog. Nemat., 89) for *F. attenuata*, from *Falco peregrinus*, 330 mm. for the female, and 115 mm. for the male, the caudal bursa of which he represents as circular. He remarks that the *Filaria* of *Strix* and of *Cecus glandarius*, referred by Rudolphi to *F. attenuata*, is a different species, but does not describe it, for want of perfect specimens. Obtained in Chester county, Pennsylvania, December, 1886, by Dr. B. H. Warren.

Three specimens, females, two inches in length, from the orbit of the Hen-hawk, *Buteo borealis*, in the collection of the Army Medical Museum, appear to belong to this species.

Ascaris tulura.—Body cylindrical, most narrowed and tapering anteriorly, of a pinkish color; mouth trilobed, the lobes together nearly as wide as the head. Female: caudal extremity nearly as thick as the middle of the body, straight; tail short, obtusely conical; as broad at base as the length. Male: caudal extremity tapering, slightly incurved, with a row on each side of minute papillæ (20 or more?); tail short, conical, ending in a spheroidal knob. (Drawing.)

One female; length 125 mm.; width of cephalic extremity a short distance from the end, 0.375; at middle of body, 1.25; near the tail, 1 mm. wide; tail, 0.25 long. One male; length 90 mm.; width at middle 0.75; tail 0.25 long; rounded end, 0.125 thick.

From the ventriculus of the Red-shouldered Hawk, *Buteo lineatus*.

This worm approximates the *Ascaris depressa* Rud., observed in many rapacious birds, but appears to be a different species. Diesing (Syst. Helmi., 156) describes the tail of the male of the former as shortly mucronate and papillose beneath, and Schneider (Monog. Nemat., 41) figures it according to that description.

Specimens obtained in Chester Co., Pa., December, 1886, by Dr. B. H. Warren.

Ascaris sulcata, Rudolphi. Body anteriorly attenuated; posteriorly more or less closely spiral; head with prominent lips. Female: tail conical, recurved from the anus, ending in a minute muero.

Male: tail conical, shortly mucronate, bialate, with a row on each side of four or five nipple-like papillæ.

Female up to 25 mm. long by 0.5 wide at middle; tail, 0.25 long. Male, 15 mm. long by 0.3 wide at middle. (Drawing.)

Numerous specimens were found tightly clinging by the mouth to the lining membrane of the stomach of *Trachemys scabra*.

Echinorhynchus caudatus, Zeder. Body narrow, cylindrical, nearly equal throughout, strongly corrugated so as to appear annulated, posterior extremity conical. Proboscis cylindrical, expanded at base, with 9 to 11 rows of strong hooks, succeeded with about 15 rows of smaller hooks. Length, from 5 lines to an inch; breadth, 0.5 to 1.5 mm. From two individuals of the Swallow-tailed Kite, *Elanoides furcatus*, in one of which they were associated with *Tænia viator*. Two specimens from *Strix nebulosa*. Florida. Dr. B. H. Warren.

Echinorhynchus hystrix, Bremser. Body cylindrical, much corrugated, widest anteriorly and minutely echinate. Proboscis clavate, with about a dozen rows of hooks. One-fourth to three-fourths of an inch long and one line wide at the fore part. Numerous specimens from the intestine of the Darter, *Plotus anhinga*. Florida. Dr. B. H. Warren.

Tænia simplicissima (drawing).—Head small, unarmed, truncate; bothria spherical, terminal, occupying the four angles; neck very long, nearly or as wide as the head, body gradually widening to the posterior third and then tapering; anterior segments transversely linear, subsequently reversed disklike, gradually longer and wider, then campanulate and gradually becoming longer and narrower. Generative apertures and ova unobserved. A number of specimens from the Cod, *Gadus callarias*, up to 20 lines by 1 mm. where widest. Two only of the specimens retained the head. (Drawing.)

Tænia Ambloplitis.—Head quadrate, spheroidal, consisting almost entirely of the four large spherical bothria, with the summit slightly prominent and conical or depressed and unarmed; neck very short or none; body compressed cylindrical, gradually widening from the head to near the posterior part, where it slightly narrows to the end; segments linear, becoming gradually longer and wider, and then more quadrate, all deeply and pretty regularly wrinkled into two or three annuli. Genital apertures obscure. Length 8 to 12 inches; in alcohol contracted to 3 $\frac{1}{2}$ to 5 inches; greatest width 2 mm.

Head 0.5 to 0.625 mm. long and 0.75 to 0.875 broad. Bothria 0.375 mm. diameter. Commencement of body 0.625 wide. Anterior segments 0.125 long, 0.625 wide; subsequently 0.375 long and

1.5 to 1.875 wide; posterior segments 0.75 long by 1 mm. wide. (Drawing.)

A number of specimens from the stomach of the Rock Bass, *Amphilophus rupestris*. Lake George, New York.

This species resembles the *Tænia ocellata* Rudolphi of the European Perch, *Perca fluviatilis*, and perhaps is the same. (Drawing.)

Tænia Micropteri.—Head large, compressed spheroidal, with four subterminal spherical bothria and a papilliform unarmed summit; neck none; body obscurely segmented, and with no obvious internal organs, posteriorly variably narrowed and obtusely rounded at the end. Length from half an inch to an inch, and about 1 mm. wide. Apparently a larval form; found in the body cavity of the Black Bass, *Micropterus nigricans*. Six worms, soft, white, and active. The longer ones of an inch would elongate to double the length, becoming proportionately narrower. The head, about 1 mm. or more in diameter, varied in length and breadth, according to contraction, sometimes one and sometimes the other being the larger. Lake George, N. Y.

Last summer while at Mt. Desert, Me., I examined a squid, *Ommastrephes illecebrosa*, with the hope of finding the singular parasite *Dicyema*. The specimen was in bad condition, and while I found none of the latter, I obtained from it several small worms, which I suppose to be the larval form of a cestode. They were yet quite active though the host was already putrescent. I suspected them to belong to *Tetrabothriorhynchus migratorius*, observed in European cephalopods, but examination showed them to be different. They moved so actively and incessantly, contracting, expanding, and writhing, that it was difficult to obtain a clear idea of the shape of the worm. It appears most nearly related with *Tænia*, and provisionally may be regarded as a larval form of this genus. Its more evident characters may be summed up as follows:

Tænia loliginis.—Head unarmed, without rostellum, quadrilobate, continuous with the neck, which is variably long and narrow or short and irregularly contracted and expanded, and is constricted from the body. Lobes of the head elliptical, contractile and expansile and becoming variably folded or corrugated, furnished each at the upper pole with a hemispherical bothria. Body about as long as the head and neck, extensile and contractile, obconic or obovate, compressed, acute posteriorly, unsegmented. No interior organs visible except a vessel along the sides of the neck and encircling the lobes of the head. Color white. Length to about half an inch; width about

1 mm. Dr. H. C. Chapman informed me that he had previously observed this parasite in the squid.

Monostomum obscurum.—Elongated elliptical, flattened, obtusely angular in front, obtusely rounded behind. Oral and genital or other apertures scarcely distinguishable. Length, 4 to 8 lines; width 1 line.

Numerous specimens in the stomach of a Jew-fish, *Megalops thrioides*. Collection of the Army Medical Museum, Washington.

Distomum Aquile.—Spatulate, cochleariform, widest behind, obtuse at both ends; mouth circular, unarmed; acetabulum sessile, about as large as the mouth. Length, 3 lines; width in front, $\frac{1}{2}$ a line; behind, 4-5 of a line. Two specimens from the trachea of the Bald Eagle, *Haliaeetus leucocephalus*. Collection of the Army Medical Museum.

Distomum hispidum, Abildgaard. Body much attenuated in advance, covered with minute recurved spines, which become obsolete at the back part. Head with a pair of alate appendages covered with stronger recurved spines, and a small group in the intervals before and behind. Mass of eggs giving the axis of the body behind a red appearance. Ova oval, 0.4 mm. long, 0.24 mm. broad.

Numerous specimens about 4 lines long by 0.5 mm. where widest behind. From the intestine of the Sturgeon, *Accipenser sturio*, of the Delaware river, at Philadelphia.

Nitzschia elegans, Baer.—Several specimens of this leech, four lines long, were taken from the gills of the same sturgeon.

[February, 1887. No. 544. See Bibliography.]

Parasite of a Bat.—Dr. Leidy remarked that it was a common opinion among country people that swallows and bats were infested with bed-bugs, and often introduced them into houses. He had convinced himself that the *Cimex* infesting the cliff-swallow was a different species from the bed-bug (Proc. 1877, 284). He had repeatedly examined bats without finding *Cimex*. On one of two small bats from Panama Bay presented this evening by Dr. Wm. H. Jones he found two singular insects, which appear to be the *Polycetenes fumarius* described by Prof. Westwood from a bat of Jamaica. They are about half of the size given for the species, but otherwise appear to agree in all respects. It has four jointed antennæ, with the first pair of limbs short and the other pair long. The insect has distinct hemiclytra.

[December, 1887. No. 548. See Bibliography.]

Bot-larvae in the Terrapin.—Prof. Leidy remarked that the habits of a naturalist often led him to observe things in our daily life which usually escape the notice of others. In our food he had frequent occasion to detect parasites which he preferred to reject, but which are unconsciously swallowed by others. While he liked a herring, he never ate one without first removing the conspicuously coiled worms on the surface of the roe, and he had repeatedly extracted from a piece of black bass or a shad a thread worm which others would not distinguish from a vessel or a nerve. While he did not object to the little parasitic crab of the oyster, he made it a point to remove the equally frequent leech from the clam. It was in a piece of ham he was eating that he first noticed the trichina, which was no doubt one of the causes that led Moses to declare the pig to be unclean; and in the hundred tapeworms he had examined from our fellow-citizens during the past twenty-five years he had ascertained that they had all been derived from rare beef. He continued: In a visit to Charleston, S. C., before the late war, at an evening entertainment, among other viands were nicely browned slices of the drum-fish, *Pogonias chromis*. A friend informed him that some portions were more gelatinous and delicate than others, and helped him to what was supposed to be one of such. On cutting into it he observed imbedded in the flesh a soft mass which appeared of enigmatic character. The following day he procured from market a drum-fish, on the dissection of which he found imbedded in the tail several egg-shaped masses about three inches long and less than an inch thick, which proved to be a large coiled worm (*Acanthorhynchus reptans*) (Proc. A. N. S. 1858, 111). This it was that gave delicacy to the dainty, and in this instance the parasite seems to enhance the excellence of the food. At another evening entertainment nearer home he partook of some stewed terrapins. Taking into his mouth what appeared to be an egg, it produced such an impression as led to its rejection. Seeming so peculiar, he tied it in the corner of his handkerchief for more convenient examination. The specimen, now exhibited, was a membranous bag, which contained thirty yellowish white maggots from 8 to 12 mm. long by 1.5 to 3 mm. broad. They are the larvae of a bot-fly, and resemble those of the *Gastrophilus* of the horse. Their characters are as follows:

Body of the larva fusiform, acute anteriorly, obtuse posteriorly, consisting of twelve segments including the head, which is armed with a pair of strong, black, hooked maxillæ; terminal segment

with a pair of trilateral oval chitinous disks, each with three spiracles; intermediate segments with numerous minute recurved hooklets, disposed in incompletely separated bands at the fore and back part of the segments.

The sac containing the larvae is about three-fourths of an inch long and half an inch broad, with a short tubular prolongation open at the extremity. It was uncertain whether the sac formed part of the intestine.

The dish of stewed terrapins was suspected to have been a mixture of the diamond-back, *Emys palustris*, and the red-bellied terrapin, *E. rugosa*. This is not the only instance of the occurrence of bots in turtles, as Prof. A. S. Packard notes the case of larvae being found in the skin of the neck of the box-turtle, *Cistudo carolina*.—(American Naturalist, 1882.)

[January, 1887. No. 550. See Bibliography.]

TAPEWORMS IN BIRDS.*

Birds are as much infested with intestinal worms as other classes of animals, and none appear to be exempt, no matter what may be the nature of their food, though aquatic birds appear to harbor a greater number of species, as exemplified by ducks and geese.

Among the parasites, tapeworms, mostly of the genus *Tænia*, are common, though less frequent than the thread worms. The domestic fowl in Europe had been reported to harbor half a dozen different species of *Tænia*, though I have as yet observed but one with us, and this but rarely. No species, I believe, has been noticed in our turkey, nor the guinea fowl and pea fowl.

FIG. 1.—Anterior extremity of *Tænia microps*. 30 diameters.

Dr. J. Van A. Carter, of Fort Bridger, Wyoming, directed my attention to the sage fowl, *Centrocercus urophasianus*, as being much infested with tapeworms. They often occur together in large numbers, sometimes so as to distend the small intestine. The young birds especially are affected; and the old birds appear comparatively exempt. Perhaps this may be due to the individuals much infested

*Journal of Comparative Medicine and Surgery, Vol. VIII.

being killed off, though the living birds infested, which were observed, appeared not to be suffering in nutritive condition. The species seems to be the *Taenia microps*, Diesing; the same which infests the Capercailzie, *Tetrao urogallus*, of Europe. Its characters are as follows: Head globose or oval, without rostellum or armature, and with a central fovea at the vertex. The four bothria spherical or oval. Neck long, variably narrower than or as wide as the head. Anterior segments, where distinct, about three times the breadth of the length: subsequently seven or eight times the breadth of the length; afterwards again about three times the breadth of the length; then nearly square; next longer than broad; and finally two or three times the length of the breadth. Segments mostly flat, or narrowly elliptical in section, but finally nearly as thick as wide, so as to be oval or nearly circular in section. Genital apertures marginal, alternating, most distinct in the middle segments. Ova, in the terminal segments, oval, colorless, with an embryo provided with three pair of spines.

Length 9 inches, greatest width $2\frac{1}{4}$ lines. Measurements of several individuals were as follows:

No. 1. Length, 28 centimeters. Head, 0.375 mm. long, 0.45 broad. Bothria, 0.225 by 0.25. Neck, 2 mm. long, 0.25 where narrowest. Anterior segments, 0.125 to 0.175, .75 to 1 mm. broad; middle segments, 1.5 long, 4.5 broad; terminal segments, 2 mm. long, 1 broad and thick.

No. 2. Length, 11 centimeters. Terminal segments, 1 mm. long, 4 broad.

No. 3. Length, 17 cm. Head as in No. 1. Neck, 2.5 mm. long. Anterior segments, 0.125 mm. long, 0.3 broad, and then 0.45 broad. One-third the length behind, 1 mm. long, 2.25 broad; terminal segments, 3 long by 1 to 1.25 broad.

No. 4. Length, 15 cm. Terminal segments, 1.5 mm. long, 4.5 broad.

No. 5. Length, 22 cm. Terminal segments, 1.5 mm. long, 4 broad.

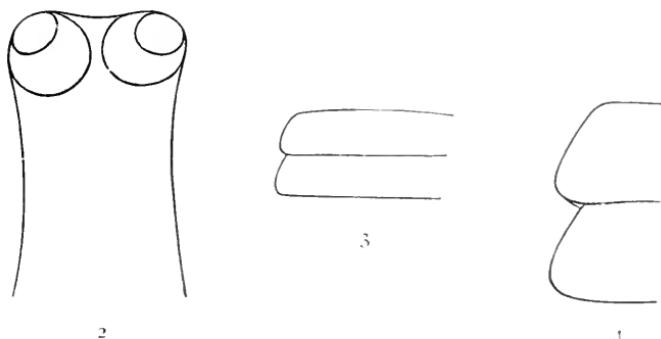

No. 6. Length, 16 cm. Middle segments, 1 long, 2.5 broad; terminal segments, 2 long, 1.5 broad, 1 thick.

No. 7. Length, 25 cm. Middle segments, 1 mm. long, 5 broad; at posterior fourth, 2 long, 3 broad; terminal segments, 3 long, 2 broad, 1.5 thick.

No. 8. Terminal segments 5 mm. long, 1.5 wide, 1 thick.

No. 9. Terminal segments 3.3 mm. long, 2 wide and thick. Ova 0.12 mm. long, 0.08 broad.

Our reed bird, or rice bird, *Dolichonyx oryzivorus*, at the time of its autumnal visit to the vicinity of Philadelphia, I have found to be very much infested with tapeworms. Every bunch of a dozen, as obtained in market, will be found to have three or four individuals with the parasite. The worms usually are found in the thin birds, while the fat ones are commonly free, thus apparently indicating by their presence an influence on the nutrition of their host.

Figs. 2, 3, 4.—*Taenia pestifera*; 2, head; 3, anterior segments; 4, posterior segments. 40 diameters.

The species formerly described by me, and since more carefully examined, presents the following characters:

Taenia pestifera.—Proc. Acad. Nat. Sci., 1855, 443. Head quadrate, scarcely defined from the neck, summit truncate, slightly prominent, flat, or depressed, unarmed; bothria large, spherical, occupying the four corners. Neck long, as wide or slightly narrowed from the head. Body gradually widening to the middle and then more or less tapering; anterior segments transversely linear, becoming gradually longer and broader; subsequently obtuseate longer and narrower.

In an apparently complete individual, $3\frac{1}{2}$ inches long, it was widest at the middle and tapering towards the extremities. Head 0.75 mm. broad; middle segments of body 1.5 broad; posterior segments 0.75 broad.

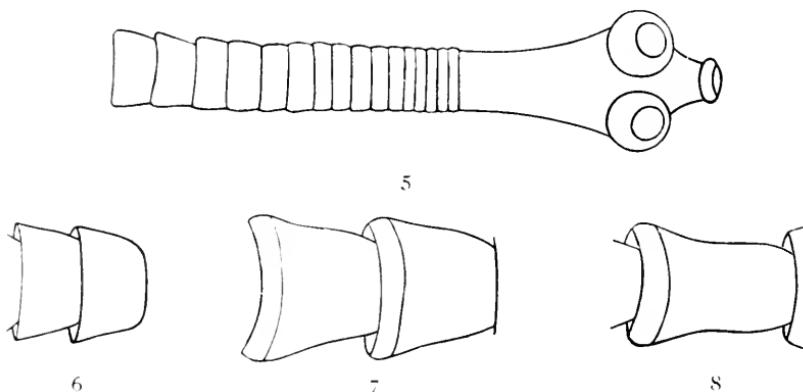

In a number of individuals the head ranged from 0.25 mm. long and 0.875 broad to 0.3 long by 1.625 broad. Posterior cuneate segments variably 0.3 to 0.375 mm. long by 0.5 to 0.75 wide.

I have seen several tape-worms, apparently of the same species, submitted to my examination by Dr. B. H. Warren, of West Chester, who obtained them from the yellow-breasted chat, *Icteria virens*.

Prof. S. F. Baird submitted to my examination a number of tape-worms obtained from the cow-bird, *Molothrus ater*, which I at first

supposed to be of the same species as the former, but comparison proved them to be different. Their characters are as follows : *Tænia urnigera* = *T. pestifera* in part, Proc. Acad. Nat. Sci., 1855, 443.

Head uniform or cruciform, summit projecting in a pedicillate rounded knob or disk, or rostellum, unarmed. Bothria spherical, prominent. Neck, short or longer, obconic. Body narrowest at commencement and gradually widening to near the posterior extremity. Anterior segments narrow, annular, soon becoming cuneate, gradually longer and wider, and then campanulate with prominent back border. Length from 1 to 2 inches, ordinarily about 15 lines ;

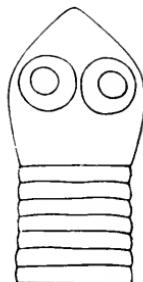

FIGS. 5, 6, 7, 8.—*Tænia urnigera* : 5, anterior part of body ; 6, 7, 8, segments from anterior, middle and posterior parts. .40 diameters.

greatest width 0.75 mm. Head, 0.4 mm. broad, with neck 0.5 long : commencement of body 0.15 wide ; anterior segments 0.1 long, 0.15 wide : later, 0.2 long, 0.375 wide : subsequently 0.25 to 0.75 long and 0.625 wide above and 0.875 at posterior border ; a terminal segment 1.375 long and 0.5 wide.

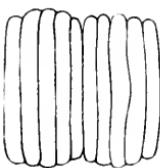

Dr. B. H. Warren, of West Chester, a zealous ornithological observer, has submitted to my examination a collection of intestinal worms, recently obtained by him during an expedition to Florida. Among these are a number of tapeworms, of which most appear to be undescribed species. They are as follows :

Tænia odiosa.—Head hemiovoid to conical, unarmed ; bothria sub-terminal, spherical, near together ; neck none ; body immediately after as wide or nearly as wide as the head : anterior segments short, linear : succeeding segments all wrinkled annularly, the more anterior band-like, the posterior barrel-shaped. Generative apertures lateral, mostly not visible. Length 1½ to 2 inches. Head 0.3 to 0.45 mm. wide ; body just behind about as wide as the head ; anterior

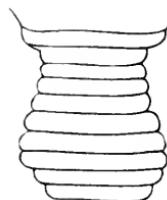

segments 0.05 long; succeeding segments 0.15 long by 1 to 1.25 wide; at widest part of body, 0.5 long by 1.625 wide; posterior segments 1.25 long by 1.25 wide. From the intestine of the quail, *Ortyx virginianus*, four birds of the same brood.

9

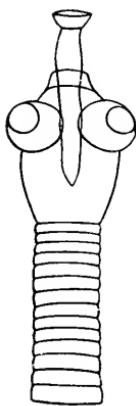

10

11

FIGS. 9, 10, 11.—*Taenia odiosa*; 9, anterior part of body; 10, 11, annulated segments from middle and posterior parts of body. 20 diameters.

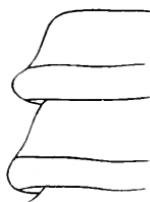

Taenia viator.—Elongate clavate, broadest behind and rounded at the extremity. Head longitudinally oval or cylindroid, with large prominent spherical bothria, and with a protrustil, cylindrical proboscis, ending in a disk, but unarmed. Neck short, obconic. Commencement of the body narrowest; early segments transverse, linear,

12

13

14

FIGS. 12, 13, 14.—*Taenia viator*; 12, anterior part of body; 13, 14, segments posteriorly. 40 diameters.

the succeeding ones becoming longer, wider, and obconicate or sub-campanulate, with thickened posterior margin. From 6 to 18 lines long by 1.5 mm. where widest. From the intestine of the Swallow-tailed Kite, *Elanoides forficatus*.

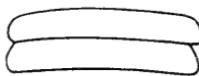

Many specimens from two birds. The worms have a yellow color; those from one bird of a bright lemon yellow, and on pressure exuding a bright deep yellow oil.

Head with proboscis, 0.7 mm. long; breadth 0.425; length of proboscis 0.2 to 0.3 long, 0.075 wide at middle, and 0.125 at terminal disk. Width at commencement of body, 2.2 to 0.225; anterior subcampanulate segments 0.175 long and 0.3 wide; others 0.15 long and 0.45 wide; posterior larger segments 0.375 to 0.625 long and 1.25 to 1.5 wide. In a specimen 15 lines long after some of the subcampanulate segments 0.15 long and 0.45 wide followed others much elongated 0.625 long by 0.15 wide in front and 0.25 wide behind. In the same specimen the posterior broadest segments were 0.625 long by 1.5 wide; and the last few segments were 0.75 long by 0.875 wide. In the largest segments the genital apertures could be distinguished in one margin, but neither ova nor penis could be detected.

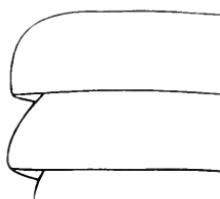

Tenia revata.—Head armed, transversely quadrate oval, with spherical bothria, variably prominent or retracted, summit convex or depressed with a broad immersed corona of minute hooks. Neck short or sometimes longer and proportionately narrower; segments

15

16

17

FIGS. 15, 16, 17.—*Tenia revata*; 15, anterior part of body; 16, 17, segments from more posterior part of body. 40 diameters.

of body varying from linear to crateriform and campanulate; the last segment half oval; genital apertures marginal, mostly not readily detected. Length from 9 lines and 1 inch to 2½ inches. Head 0.375 mm. broad; neck 0.3 broad; widest part of body 1 to 1.25 mm. broad.

Intestine of pileated woodpecker, *Hylotomus pileatus*.—From six birds. In different specimens the measurements were as follows: Head, 0.325 to 0.5 mm. wide; neck, 0.125 to 0.3 wide; anterior segments linear, 0.0725 long by 0.25 wide; succeeding, reversed cup-like and variable in proportion of breadth and length according to degree of contraction, 0.175 long by 0.3 wide, or 0.2 long by

0.375 wide, or 0.25 long by 0.75 wide; widest segments reversed crateriform, 0.5 long by 1 wide, or 0.3 long by 1.25 wide, or 0.25 long by 1.5 wide; posterior segments campanulate, 0.375 long by 0.625 wide, or 0.5 long by 1 wide, or 0.75 long by 1 wide.

In a much contracted specimen $1\frac{1}{2}$ inches long, with the widest part 1.75 mm. broad and proportionately thickened, the head was 0.4 wide, the neck 0.25, the anterior cup-like segments 0.15 long by 0.2 wide; the posterior widest and thickest part with segments 0.25 long by 1.75 wide; the posterior campanulate segments 0.75 long by 1 wide. In another much contracted specimen 30 mm. long the head was 0.325 mm. wide; the short neck 0.225 wide; the widest part with segments 0.3 long and 1.625 wide; the terminal segments 0.375 long by 1.25 wide. In a much elongated specimen of $2\frac{1}{2}$ inches the head was 0.375 mm. wide; the neck 0.2 wide; the anterior cup-like segments 0.2 long and 0.375 wide; succeeding segments 0.25 long and 0.75 wide; next 0.75 long by 1 wide, and terminal ones 0.5 long by 0.8 wide.

In some fragments with broad segments the genital apertures were seen to be distinctly marginal and with a small penis having the summit protruding.

Tænia simpla.—Head short, transverse discoid or hemispherical, slightly prominent or depressed at summit, unarmed; bothria spherical, occupying the four corners; neck none; body at commencement variably narrower than the head; anterior segments

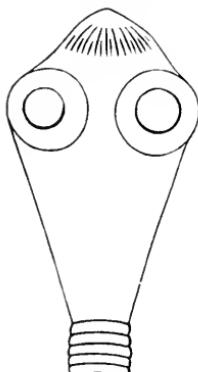

FIG. 18.—*Tænia simpla*; anterior part of body. 40 diameters.

linear, becoming gradually longer and broader and decidedly campanulate. Many fragments, from which the worm is estimated at about 18 lines.

Intestine of the Chuck-will's-widow, *Antrostomus carolinensis*.—Head, 0.2 mm. wide, 0.1 long. Body succeeding head, 0.175 mm. wide. Campanulate segments, 0.375 long by 0.5 wide; subsequently same length and double width. Some of widest segments 0.25 mm. long by 1.25 wide.

Tænia aurita, Rudolphi.—Head urn-like or doubly conical, summit armed with a double circle of alternating hooks, long and short; bothria lateral, spheroidal, neck obconic; body long, clavate, widening behind and abruptly rounded at the end; anterior segments linear, then linear campanulate, and then more strikingly campanulate

with the posterior border thickened. Length to about 2 inches. Head and neck 0.3 mm. long, 0.2 wide; narrowest portion of body 0.06 to 0.1 mm. wide; near posterior extremity to 1 mm. wide. In a small and apparently complete individual of 10 lines, the head was 0.225 mm. long; commencement of the body 0.1 mm. wide; three lines behind the head the segments were 0.075 mm. long by 0.25 wide; near the middle 0.15 long and 0.75 wide. Terminal segments 0.2 long by 0.825 wide to 0.25 long by 0.75 wide. A posterior frag-

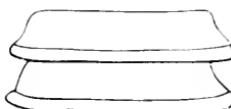

19

21

22

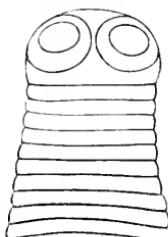

Figs. 19, 20, 21, 22.—*Taenia aurita*; 19, head, 125 diameters; 20, hook, 500 diameters; 21, 22, segments near middle of body, 40 diameters.

ment of 15 lines had the anterior campanulate segments 0.125 mm. long by 0.5 wide and the posterior segments 0.35 mm. long by 1 wide. Bothria 0.08 mm. diameter. Long hooks 0.048 long; short ones 0.028.

Taenia unilateralis, Rudolphi.—From the intestine of the blue heron, *Florida cerulea*. Previously described from the same bird from Brazil. Head very small, consisting of four small bothria terminating the body, with a minute nail-like rostellum. Neck none. Body rapidly widening from the head. Anterior segments linear; posterior segments short cuneate, with a minute cylindrical penis projecting from each segment, all on the same side. From the intestine of the green heron, *Butorides virescens*. Many fragments. In the only one with a head, 2 inches in length, the head was 0.3 mm. wide; the rostellum 0.15 long; the widest part of the body 3 mm.

Taenia Oporonis.—Head hemispherical; bothria spherical, occupying the sides of the former; neck none; body at commencement as wide as the head and thence gradually widening to the posterior third and then diminishing. Anterior segments linear and trans-

versely deeply striae; subsequently reversed dish-shaped and finally reversed bowl-shaped. Length about 18 lines. Head 0.375 mm. to 0.45 broad; widest segments 0.125 long by 0.75 wide; posterior segments 0.2 by 0.625 wide. Several specimens and fragments from the intestine of the Kentucky warbler, *Oporornis formosa*.

23

24

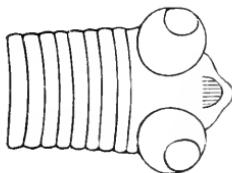

25

Figs. 23, 24, 25.—*Taenia oporornis*; 23, anterior part of body; 24, 25, segments posteriorly. 40 diameters.

A tapeworm from the robin, *Turdus migratorius*, obtained at West Chester by Dr. Warren, seems to be the same as the *Taenia angulata*, Rudolphi, infesting European species of thrushes. Its characters are as follows:

Head broader than long, with spherical bothria at the lateral angles; a short conical rostellum enclosing a conical papilla closely covered with two rows of alternating recurved hooks. Neck none. Body at commencement nearly as wide or as wide as the neck, with

26

27

Figs. 26, 27.—*Taenia angulata*; 26, anterior part of body; 27, posterior segments. 40 diameters.

linear segments; subsequently obcuneate, becoming gradually wider; the widest subcuneate twelve times as broad as long. Estimated to be about 2 inches in length, with the greatest breadth about 3 mm.

In addition to the foregoing, I have observed *Taenia variabilis*, Rud., in our woodcock, *Philohela minor*, previously described from various European wading birds, and *Taenia scolopendra*, Diesing, in the horned grebe, *Podiceps cornutus*, previously described from a Brazilian grebe.

[February, 1888. No. 553. See Bibliography.]

Chaetopterus from Florida.—Prof. Leidy directed attention to specimens which were collected in the trip of Prof. Heilprin and Mr. Willcox, at the mouth of the Manatee River. The species appears to be the *Chaetopterus pergamentaceus* of Cuvier, originally described from specimens from the West Indies. It is a remarkable form. It belongs to the Tubicolæ, or tube-living worms, but, unlike most of these, is devoid of the numerous cephalic appendages, or tentacles and gills. The tube is membranous and laminated in structure, and it has the appearance of parchment. The two tubes collected are 16 inches long by three-fourths of an inch in diameter and tapering toward the ends. An incomplete worm, not well preserved on account of its delicacy, in its present condition is 9 inches long and appears very narrow in comparison with the capacity of its tube. The anterior division of the body, about an inch long, is flattened and about half as wide, but narrowing behind, and is composed of eight podal segments provided with dense bunches of lustrous golden setæ. The succeeding segment, long and narrow, is provided with a pair of wing-like appendages an inch long and each furnished with two bundles of diverging setæ. Then follow five long, narrow segments with large membranous appendages, without setæ. The terminal segments, of which 15 remain in the specimen, are furnished with pairs of long pointed appendages with bundles of setæ.

[February, 1888. Ibidem.]

Cirolana Feasting on the Edible Crab.—Prof. Leidy stated that on last Saturday, having occasion to go to Beach Haven, N. J., during a leisure half-hour stroll along the shore he noticed here and there a dead crab, *Callinectes hastatus*, lying on the sand near the last high-tide mark. The crabs observed happened to be all females, and they appeared to have died recently, as some were quite fresh and showed no signs of decomposition. Others, broken open by removing the carapace, were found to have the body cavity swarming with a living isopod, the *Cirolana concharum*, which had preyed upon the organs and were variously colored by the food with which they were gorged. From a single crab there were taken 108 of the Cirolana, ranging from 15 to 22 mm. in length by 5 to 7 mm. in breadth.

The isopod is grayish translucent above and whitish translucent beneath, and centrally variously colored, brown, black, red, or yellow, from the food contents. The dorsal plates are minutely

dotted, black or brown, in bands. The eyes are triangular, with rounded angles, and black. The antennæ are nearly double the length of the antennules. The mandibles are furnished with a strong brown tricuspid molar. The caudal plates or telson are triangular, with a blunt, slightly emarginate apex, and with a pair of spines each side of the latter. The isopod has been observed by Stimpson at Charleston, S. C., and by Harger at Vineyard Sound, Mass., but has not previously been reported from the coast of New Jersey. Three isolated specimens of the same were picked up on the shore of Beach Haven the last summer.

On Bopyrus palæmoncticola.—Prof. Leidy also presented numerous specimens of the prawn, *Palæmonetes vulgaris*, infested with the parasite *Bopyrus palæmoncticola*, obtained at Beach Haven, N. J. From about two quarts of the prawn caught for fish-bait upwards of fifty contained the *Bopyrus*.

[February, 1888. No. 555. See Bibliography.]

Reputed Tapeworm in a Cucumber.—Prof. Leidy stated that several years ago his colleague in the university, Prof. Wm. Goodell, submitted to his examination a tapeworm which he received from a correspondent, with the label "From the middle of a cucumber preserved in brine. S. E. Robinson, West Union, Iowa, May 29, 1876." The specimen appears to be complete, and in its present condition, preserved in alcohol, is about eight inches long. The head is large, spheroid, provided with four small equidistant hemispherical bothria, and surmounted by a prominent crown, with a double circle of strong hooks. The neck is a slight constriction, whence the body rapidly widens and again tapers behind. The anterior segments are transversely linear, with a gradually increasing length and more acute and prominent lateral ends; the middle segments are about twice the breadth of the length and slightly campanulate, and the posterior segments are proportionately longer and narrower. In the latter the uterus is distended with eggs only at their anterior portion.

The hooks are partially lost on one side of the crown, and it is estimated that there were about 40 or more.

The head is .875 mm. broad; the crown of hooks .625 mm.; the neck .8 mm.; at the middle of the body six segments together are 1 cm. long and 3.5 mm. wide; the terminal segments are about 4 mm. long and 2.5 mm. wide. The eggs measure from .032 to .036 mm.

While it cannot be admitted that the worm belonged to the cucumber, nor is it clear how it reached this position, it is a question as to the species. It bears a near resemblance to the *Taenia crassicollis* of the Cat, but is not more than half the size of this as it ordinarily occurs.

In comparison with a complete specimen of the latter, six inches in length in the contracted condition as preserved in alcohol, we find the following measurements :

	T. of the cucumber. mm.	T. crassicollis. mm.
Breadth of head.....	.875	1.875
Breadth of crown of hooks.....	.625	1.
Breadth of neck8	1.25
Breadth of middle segments.....	3.5	6 to 8
Length of middle segments.....	1.66	1.
Breadth of terminal segments.....	2.5	3.5
Length of terminal segments.	4.	5.

[March, 1888.]

Habit of Cirolana concharum.—Prof. Leidy said that he yesterday went to Atlantic City, in the expectation of finding interesting specimens cast ashore in the recent storm, but there proved to be nothing. He picked up a few recently dead Lady-crabs, *Platyonichus ocellatus*, and found in them a number of the *Cirolana concharum*, feasting upon the flesh and other parts, as he had previously noticed them feeding on the edible crab. (See page 80, Proceedings 1888.) From these observations it would appear to be the usual habit of the *Cirolana* to prey on dead crabs and probably other animals.

[March, 1888. No. 556. See Bibliography.]

Parasites of the Striped Bass.—Prof. Leidy exhibited numerous specimens of a minute crustacean parasite from the gills of the Striped Bass or Rockfish (*Labrax lineatus*), brought to our market. He said it is a common parasite and he had been familiar with it since 1871. It was described by the Danish naturalist, Dr. Henrik Kroyer, under the name of *Ergasilus labricis*, obtained from the same fish at Baltimore (Danske Naturh. Tids., 1863-'64, 303, Tab. ix, Fig. 2). Common as it seems to be, Mr. R. Rathbun, in his published list of the parasitic Copepoda from American waters, says he had not observed it (Proc. U. S. Nat. Mus., 1884, 483). The little crustacean lives suspended on the outer surfaces of the gills, where it is conspicuous from the white color of its thorax and egg-pouches on the red color of the gills. The length of the parasite together with its egg-pouches is 2.125 mm.; without the latter 1.25 mm.

Prof. Leidy further exhibited portions of two intestines of the same fish, with numerous attached worms pertaining to *Echino-rhynchus proteus*, which infested many fishes, both of fresh and salt water, of Europe. It is not only a frequent and abundant but a constant parasite of our Striped Bass. It ranges from 5 lines to an inch in length. The young ones are white; the older have the body yellow, bright orange, or brownish orange, with a white neck and proboscis, which together are one-fourth the entire length. Diesing attributes to the proboscis 8 to 10 rows of hooks, but Dujardin gives double the number, and this accords with the condition observed in our specimens. The parasite lives in the large intestine with the proboscis and neck together embedded in the wall and the body suspended in the cavity. The proboscis and bulbous commencement of the neck together protrude externally and form on the outside of the intestine brown pyriform tumors, giving to the organ a peculiar tubercular appearance. The worms exhibit the following characters: Body widest at the commencement, where it is rounded and slightly constricted from the rest, which tapers to the posterior obtuse end. Proboscis cylindrical but expanded at the middle and base. Neck very long, bulbous at the commencement, becoming narrower and cylindrical and a little dilated at the base; smooth throughout. Length of a large one 24 mm.; proboscis and neck 6 mm.; proboscis 1.25 mm. long, 0.175 thick; 0.25 at middle expansion; bulb of the neck 1 mm., narrow part below 0.375 thick, at base 0.5 thick. Body at commencement 2 mm. thick, near posterior end 1 mm. thick.

[March, 1888. No. 558. See Bibliography.]

Trematodes of the Muskrat.—Prof. Leidy stated that in the collection of the Academy there is a vial labeled, "Worms from the duodenum of the Muskrat." There are 25 worms, and in their present condition they are pale brown, bordered by dark brown, and measure from 12 to 18 mm. long by 1 to 1.5 mm. broad. If not identical, they are closely allied to *Distomum echinatum*, which in the mature state lives in ducks and other water birds and in the larval state in fresh-water snails. The Muskrat eats the latter, so that it may likewise become infested in the same manner as the ducks, and this would also seem to make it probable that the parasite is the same. Dujardin, Wedl, and others describe *D. echinatum* as having the fore part of the body echinate, which is not the case with the Distome of the Muskrat, though in both the head is armed in the same manner and with the same number of spines. Its characters are as follows:

Body long, flattened, band-like, with the neck tapering and the tail obtusely rounded. Head reniform, with a coronet of strong, straight spines—from 30 to 36. Ventral acetabulum much larger than the head, situated at the base of the neck a short distance behind the latter, spherical. Body of nearly uniform width. Oral acetabulum small; pharynx oval; intestines simple and narrow. Genital orifice immediately in advance of the ventral acetabulum; cirrus exsert to one side, curved and smooth; testes situated almost midway between the ventral acetabulum and tail; oviducts median behind the ventral acetabulum; ova oval, yellow; vitelline glands large and conspicuous, racemose, extending along the intestines from the ventral acetabulum to the end of the tail.

Head 0.5 to 0.6 mm. broad; spines about 0.1 long by 0.02 thick; oral acetabulum 0.25; pharynx 0.3 long, 0.225 wide; ventral acetabulum 0.875 to 1.25. Ova 0.1 long by 0.072 broad.

Since the above communication a collection of worms from the small intestine of a Muskrat has been received. Eighteen of the worms pertain to the supposed *Distomum echinatum* and range from 18 to 25 mm. long. In all, the fore part of the body to a short distance behind the ventral acetabulum is finely echinate, while the rest is smooth. Two other worms appear to belong to *Amphistomum subtricatum*, 12 and 15 mm. long, a parasite previously observed only in the Beaver of Europe.

[March, 1888. No. 559. See Bibliography.]

Entozoa of the Terrapin.—Prof. Leidy stated that he had on one occasion examined eight of our much esteemed food Terrapins to ascertain the character of their parasites. All were found to be infested with an *Echinorhynchus*, living in the small intestine and clinging by the thorny head to any part of the canal. The worms range from six to sixteen lines in length and in numbers from five to upwards of two hundred. The species is *Echinorhynchus hamatus*, originally described from several of our fresh-water turtles. (See these Proceedings, 1856, 48.)

In three of the Terrapins occurred a red thread worm, also living in the small intestine and associated with the former and, like them, clinging by their armed mouth to the mucous membrane. The species is the *Cucullanus microcephalus*, the males up to nine lines, the females from twelve to sixteen lines. In one Terrapin there were eight, in a second over a hundred, and in the third upwards of several hundred. They extended all along the intestine, but were

most numerous at its upper part. The females are viviparous and contain living young.

In one Terrapin only, also in the intestine, there were two flukes, the *Amphistomum grande*, about half an inch long.

In the bladder of another Terrapin there was a single *Polystomum* 3.5 mm. long, probably *P. oblongum*, first described by Prof. Wright, of Toronto, from an individual obtained from the bladder of the Musk Turtle, *Aromochelys odoratus*.

In another Terrapin he had found four Polystomes, of which three were in the throat and the other in the nose. These pertain to a different species from the former, and may prove to be the *Polystomum ocellatum*, found in a similar position in the European Turtle, *Emys europea*. At the genital outlet of *Polystomum*, situated ventrally at the fore part of the body, the cirrus is surrounded by a circle of hooks. In *P. integerrimum*, the species best known and found in Europe, living in the bladder of frogs, the genital circle is composed of eight hooks. Prof. Wright ascribes sixteen hooks to the circle of *P. oblongum*, and this accords with the number in the Polystomum from the bladder of the Terrapin. In the other Polystomes of the latter he found the circle to be composed of thirty-two hooks. Siebold says there are forty hooks to the circle in *P. ocellatum*. Dr. Zeller figures the latter from a sketch of Siebold, in which the caudal disk is represented as having two large hooks and eight small ones between the posterior pair of bothria. In the allied Polystomes of the Terrapin the number and arrangement of the hooks of the caudal disk is the same as represented in Prof. Wright's figure of *P. oblongum*. If, then, we have a correct record of the facts, the Polystomes of the fauces of our Terrapin may be regarded as another species, which may be distinguished as follows:

Polystomum coronatum.—Body when elongated lanceolate. Caudal disk wider than the body, cordiform, with three pairs of bothria and with the body attached between the anterior two pairs; changeable in form to oblong, circular or quadrate; with three pairs of minute hooks between the anterior pair of the bothria and with a larger pair and two small pairs between the last pair of bothria. Genital aperture with a circular or a transverse oval coronet of thirty-two hooks of equal length. No eyes visible. Length elongated from 4 to 6 mm.; contracting to about half the length and widening proportionately.

Besides the foregoing, there was found in the intestine of one of the Terrapins a little Distome, of 3 mm. length, which, though mature, he had not the leisure to examine. He also observed in the

throat of one a number of little anguillula-like worms, which he likewise did not examine.

In all the Terrapins the flesh, liver, and other parts than those above mentioned were entirely clear of parasites. Therefore, in preparing these animals for food, it is easy to free them from the latter by rejecting the head, intestines, and bladder; or if it is thought desirable to use the intestines, they should be slit open and cleansed of the contents.

Prof. Leidy added that he had recently found in the collection of the Academy a bottle labelled "alimentary worms in terrapin." These proved to be seven bot-larvae like those described and exhibited at a former meeting. (See Proc., 1887, 393.)

[April, 1888. No. 560. See Bibliography.]

A Crustacean Parasite of the Red Snapper.—Prof. Leidy remarked that in the examination of the fish called the Red Snapper, *Lutjanus Blackfordi*, brought to our market from Florida, he had observed a curious crustacean parasite adhering to the throat about the pharyngeal bones. It appears to be an undescribed species of *Anchorella*, which, from its having a bundle consisting of half a dozen posterior appendages, including a pair of large egg pouches, may be named *A. fasciculata*. The animal is milk white, though in the fresh condition the egg pouches are slightly reddish, and it is about half an inch long, including the latter. The body is pyriform, with its long axis in the same line with the single suspensory arm, and with the head and neck curved outward and a little downward to one side. The head is bird-head-like in shape, with beak directed upward and furnished with two pair of minute maxillipeds. The suspensory arm, or brachium, about as long as the head and neck together, is straight and is surmounted by a button, which is sessile and internally striated. At the base of the brachium on each side there is a minute papilla. The posterior appendages consist of two long cylindrical egg pouches, and on each side two much shorter sausage-like pouches. The adjoining figure is an outline of the parasite magnified six diameters. Twenty-five were obtained from one fish. Measurements of a specimen are as follows: Length of body with brachium 2.5 mm.; length of brachium 1.25; of head and neck 1.75; head 1 by 0.625; breadth of body 1.375; length of egg pouches 4, thickness 0.625; length of short pouches 1.625 and 1.25. Clinging to the head of one of the females of the *Anchorella* was a minute male measuring 1.125 mm. in length. With the Anchorellæ was found a single specimen of *Caligus*, which closely resembles the *C. nanus*,

Kroyer, if it is not identical with it. It is 1.125 mm. long. The cephalothorax is about as wide as it is long, 1.875 mm.; the first abdominal segment is obcordate 1.5 long and 1.25 wide; and the second long and narrow 1.375 long and 0.375 wide. The cephalic bothria 0.25 diameter.

[April, 1888. No. 562. See Bibliography.]

PARASITIC CRUSTACEA.

Attached to the shark, *Odontaspis littoralis*, caught at Beesley's Point, New Jersey, above indicated, on each side of the mouth, hanging from the upper lip, were a number of lernean parasites, and these were thickly covered with a hydroid parasite. The lernean appears to be an undescribed species, and may therefore be distinguished by the following name and characters:

Lerneonema procura.—Animal pale yellowish. Head horizontal, semi-oval, convex above, with three short, blunt occipital tubercles, fore part convex, excavated beneath and enclosing the mouth, antennæ, and maxillipeds; neck long, linear, cylindrical; body short, fusiform, and truncated behind; tail longer than the body, linear, cylindrical. Egg pouches long, linear, cylindrical. Length 70 mm.; including egg pouches, 90 mm. Head 3 mm. long; neck 30 to 45 mm. long, 0.375 thick; body 10 to 12 mm. long, 1.75 thick; tail 12 to 15 mm. long, 0.5 thick. Egg pouches 20 mm. long, 0.25 thick.

The hydromedusarium appears to belong to *Eucope parasitica*, found in the same manner by A. Agassiz, in a lernean of *Orthagoriscus mola*. Some of the stems rise from the creeping root from 5 to 8 millimeters, with short branches, two or three ringed. The polyp-cups are 0.375 mm. long by 0.25 wide. The stems are 0.1 mm. thick, and the alternate lateral branches about 0.2 long.

From the fins of a Shark, also caught at Beesley's Point, but the name not ascertained, there was obtained a single specimen of a lernean, which nearly resembles the *Perrisopus dentatus*, of Steenstrup and Lutken. It is 5 mm. long. The cephalothorax is a little smaller than the abdominal segment, and between them are three pairs of dorsal lobes which completely cover the space. The egg pouches are linear and 0.25 mm. thick.

[May, 1888. No. 563. See Bibliography.]

Parasites of the Rock Fish.—Dr. Leidy stated that he recently had examined the gills and entrails of a Rock Fish, *Labrax lineatus*, weighing 20 pounds, on which he made the following remarks:

The gills were swarming with the little crustacean parasite *Ergasilus labracis*. In many of these the thorax and egg-sacs were opaque milk-white, but in most of them the latter were more translucent and of a blue color. This difference is due to the development of the embryos, within which there appears blue pigment.

Attached to the gills there were three opaque milk-white fluke-worms, and a fourth of the same kind was embedded in the muscular coat of the pharynx. These appear to pertain to an undescribed species, and may therefore be distinguished by the following name and description :

Distomum galactosomum.—Opaque milk-white, depressed, spatulate, narrowest in advance, obtusely rounded at both extremities, dorsally convex, ventrally flat. Head rounded truncate or transversely oval discoid, with prominent margin, unarmed ; neck short, slightly widening to the ventral acetabulum, which is sessile, larger than the oral acetabulum and with its orifice appearing triangular ; posterior part of the body elliptical, in movement expanding and becoming thinner and translucent and concave beneath, with the opaque white intestine on each side shining through. At rest about 6 mm. long by 2 mm. wide, elongating to 12 mm. by 2.5 mm. wide posteriorly and 1 mm. at the base of the neck.

After being killed in dilute alcohol the specimens remained of spatulate shape, 6 to 8 mm. long, 2 mm. wide behind. The oral acetabulum 0.625 broad ; the ventral acetabulum, situated 1.375 mm. back of the summit of the head, was 0.875 broad.

When the animal was in motion and expanded the posterior portion of the body to such an extent as to render it translucent, the intestine on each side became especially conspicuous through its white opacity. The intestines extended directly from the minute pharynx to the caudal extremity, more or less tortuous, according to the degree of elongation or shortening of the animal. They are widest back of the ventral acetabulum and are sacculated. In the expanded condition of the body, by transmitted light, it exhibited a minutely reticular appearance, the lines of the rete being more opaque white and apparently according with a capillary net communicating laterally with the vessels proceeding from the caudal vesicle. The opaque white appearance of the body seems to be due to the presence of granules of calcium carbonate, for the application of acetic acid caused their disappearance with the evolution of bubbles of gas, and the body became more uniformly translucent without, however, affecting the white opacity of the intestines. The generative apparatus appears to be undeveloped, as no distinct

organs were observable. At the middle of the posterior portion of the body, in the usual position of the testes, there appeared a single clearer spot, and in advance of it a clearer streak. The character of these he had not determined.

Many worms, the *Echinorhynchus proteus*, clung to the interior of the intestine its whole length, but they were not so numerous as nor larger than they are commonly found to be in smaller individuals of the same fish.

Of two other large Rock-fish examined, weighing each about a dozen pounds, one was free of parasites of all kinds, and in the other there were only a few of the little crustacean, *Ergasilus*, adhering to the gills; and within the abdominal cavity, adherent to the stomach, closely coiled and encysted, a dozen nematoid worms, the *Agamoneema capsularia*, a common parasite of the shad and herring. Neither of the fish contained a single *Echinorhynchus*, a remarkable circumstance, for he had never before examined a Rock-fish without finding this parasite present.

[**May. 1888. No. 564. See Bibliography.]**

Louse of the Pelican.—Prof. Leidy remarked that the admirable monograph of E. Piaget, "Les Pediculines," a large work, with supplement, in three quarto volumes, illustrated, and published in Leyden from 1880 to 1885, presented tonight, had reminded him that he had formerly made a communication to the Academy on an insect of the kind, which was remarkable on account of its living in the pouch of the Pelican. A brief description of the louse, under the name of *Menopon perale*, is given in the Proceedings, 1878, p. 100. Mr. Piaget describes two species of *Menopon* from Pelicans, *M. titan*, living on *Pelicanus onocrotalus* and *M. consanguineum*, which he observes appears by preference to infest the interior of the great pouch of *P. crythrorynchus*. He remarks of the latter that it probably has some relation with *Menopon perale*, and regrets the insufficient description of this species for comparison. Prof. Leidy continued that M. Piaget's figures of *Menopon titan* and *M. consanguineum* appear so nearly alike and resemble so closely *M. perale* that from his own judgment he would have regarded them as all of one species. In 1878 he had prepared a more detailed description, with figures of *Menopon perale*, intended for publication in one of the Government reports, but, as it was not called for, it was forgotten until he was reminded of it by the appearance of the great work of M. Piaget. *Menopon perale* was named from specimens submitted to him by Prof. Wyman, who obtained it from the pouch of *Pelicanus trachyrhyn-*

chus, in Florida, and others obtained by Dr. E. Coues from the same bird, on the Red River, near Pembina, Dakota. Dr. Coues, in his "Birds of the Northwest," U. S. Geol. Surv., 1874, 587, says of the White Pelican: "I took a female in very poor flesh, with worn, harsh plumage, which was attributable to a disease of the pouch. On the inside of this organ was fastened, in patches, great numbers of a louse, which produced an induration, ulceration, and finally perforation of the membrane."

The characters of *Menopon porale* as drawn from his original manuscript are as follows: Head wider than long, transverse reniform, pale brown, with a darker patch and a crescentoid black spot between the clypeus and temple, fringed in front with short hairs, with a longer tuft at the posterior lateral lobe, and a row of eight along the posterior concave border. Antennæ concealed beneath the head, with the terminal joint largest and oval. Maxillary palpi cylindrical, reaching to the lateral border of the head, four jointed. Mandibles strong, deeply two-toothed, black. Eyes two, close together on each side of the lateral border of the head. Prothorax narrower than the head, rounded hexagonal in outline and produced laterally in a strong conical point, pale brown above, with a darker band crossing the middle and darker at the lateral borders, smooth. Metathorax as wide as the head, bell-shaped in outline, with lateral rounded angles; crossed by a row of hairs. Limbs well produced: anterior femora short and robust; the posterior two nearly twice as long as the former and darker brown in color. Tibiæ with a spur at the distal extremity. Tarsus with an ovate appendage at the proximal extremity, and a single hair at the distal extremity. Ungues strong, black. Abdomen long elliptical, nearly twice the length of the head and thorax, and widest at the fourth segment. Segments of nearly equal length, the last one mammiform, all with a wide chestnut brown band, and a row of short hairs emanating from clear circular bases. Last segment with an additional tuft of hairs on each side.

Entire length $2\frac{1}{4}$ lines; color translucent whitish and transversely striped with chestnut brown. Smaller individuals paler in color, with narrower stripes of brown.

In an individual 4.75 mm. long, the head was 0.75 long and 1 mm. broad; the prothorax 0.55 long and 0.825 broad; the metathorax 0.625 long and 1 mm. broad; the abdomen 2.875 long and 1.25 mm. broad.

Attached singly or in groups up to fifteen or more between the folds of the lining membrane of the pouch of *Pelicanus trachyrhynchus*.

[July, 1888. No 569. See Bibliography.]

PARASITES OF THE SHAD AND HERRING.*

With the view of ascertaining the parasites of the shad, *Alosa sapidissima*, I examined the entrails of fifty fish brought to our market from the rivers of the south and from the Delaware. Most of them were found to be infested with two nematoid worms, the *Agamoneema capsularia*, Diesing, and the *Ascaris adunca*, Rudolphi, and all of them with the larva or scolex of a cestoid worm, which I propose to distinguish as *Gymnoscolex picta*. I also examined half a dozen of the closely allied fish, the common herring, *Clupea haren-gus*, in which I also found the *Agamoneema capsularia* and *Gymnoscolex picta*, but not the *Ascaris adunca*.

Agamoneema capsularia, Diesing.—This worm, known only in the immature sexual condition, is a frequent and common parasite of many fishes. Called by Linnaeus the *Gordius marinus*, it has been described under various other names by different authors. Observed in Europe as a parasite of the herring, it has also been there noticed in the salmon, mackerel, cod, turbot, halibut, and other fishes. In our herring it appears to be a constant parasite, sometimes few and often in considerable numbers. It occupies the abdominal cavity among the viscera usually encysted in the peritoneum about the stomach and intestine, and especially the pyloric appendages, and less frequently on the liver and roes. It often forms flat and close spiral coils, lying on the viscera or appended to them. Frequently it is observed free and incessantly wriggling; but in this condition I suspect the worm has escaped from its cyst after the death of the herring.

The *Agamoneema* is also a common parasite of the Shad, and though usually occurring in small numbers, appears to be as constant as in the Herring. Mostly, too, it is larger than in the latter, and is found in the same positions and conditions. It is most frequently observed in conspicuous coils, appended to the viscera, and especially to the caecal extremity of the stomach. It was found in every Shad examined, from three to a dozen or more.

The characters of the *Agamoneema* of the Herring were as follows: Body slender, most tapering in advance, translucent white, and often with the intestines brownish, but in others white. Head rounded, truncate and bordered by conical papillæ, with the mouth unarmed, but furnished to one side with a minute conical spine attached by a broad base. Tail short, conical, incurved, blunt, but terminating in a minute mucro.

* Journal of Comparative Medicine and Surgery.

Length, 10 to 18 mm.; thickness, 0.25 to 0.375 mm.; tail, 0.12 to 0.24 mm. long.

The œsophagus is long and cylindrical and is defined from the intestine by a marked constriction. The intestine has a long translucent diverticulum directed backward from its commencement, and another more opaque directed forward along the opposite side of the œsophagus.

The *Agamoneema* of the Shad ranged from 15 to 25 mm. by 0.3 and 0.5 to 0.625 mm. in thickness, with the tail 0.125 to 0.25 mm. In the smaller, translucent individuals the alimentary canal appeared to be like that in the *Agamoneema* of the Herring, but in the largest individuals I am uncertain whether the condition is the same.

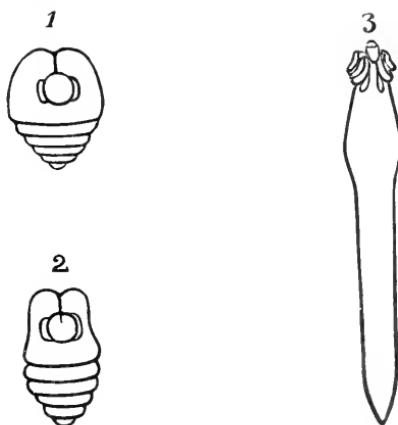

The number of papillæ to the head of *Agamoneema* appears to be three, but of this I could not satisfy myself. Wedl describes the *Agamoneema* of the Mackerel as having the mouth armed with a conical tooth, which is capable of being protruded and retracted within a sheath. (Sitzungsbl. Akad. Wiss., 1855, 18, Taf. III, Fig. 24.) In the worms under examination, I could see no such tooth, but to one side of the mouth, as above described, a little conical spine fixed by a spreading base, and commonly projecting obliquely forward and outward.

Ascaris adunca, Rudolphi. This worm was originally described as a parasite of the European Shad, *Alosa vulgaris*. It is a frequent though not a constant parasite of our Shad, and commonly appears to occur few in numbers. From two to half a dozen were found in three-fourths of the Shad examined. It occurs in the intestine, pyloric appendages, and less frequently in the stomach. In general appearance it resembles the *Agamoneema*, but is readily distinguished by its large lips. Its characters are as follows: Body cylindrical, thickest posteriorly and tapering in advance; caudal extremity incurved. Lips large and conspicuous, tail short, conical, acute. Male with the caudal extremity spirally inrolled; with a pair of curved spicules.

Female 12 to 40 mm. long; 0.3 to 1.125 mm. thick; tail 0.125 to 0.25 mm. long. Male, 20 to 30 mm. long, 0.45 to 0.55 mm. thick. In the smaller individuals the body is more uniformly cylindrical or less tapering in advance. This worm I formerly confounded with its associate *Agamoneema* (Proc. Acad. Nat. Sci. Phila., 1856, 55).

Gymnoscolex picta.—In all the Shad and Herring subjected to examination there occurred a larva or scolex of a cestoid worm, which, though closely resembling the *Scolex polymorphus*, I suspect to be different, and have therefore given it another name. The lat-

ter species is attributed to numerous marine fishes of European seas, but among them neither the Shad nor Herring have been indicated. *Scolex picta* appears to occur almost constantly in our Shad and Herring. It was found along the course of the intestine, but especially in the pyloric portion and in its appendages. Commonly not very numerous, sometimes there were but few, but generally from about a dozen to fifty and upwards. In the abundant mucus of the viscera they appear as white granules, about the size of ordinary sand grains. Their characters are as follows: In the quiescent condition with the head withdrawn into the body; spheroid, ovoid, ovate, or cordate; in front rounded or truncate and more or less emarginate or projecting in a bipapillate manner; posterior third conical, obtuse or sub-acute, and annularly rugose. In the active condition with the head projected, clavate, elongating and becoming linear behind with the disappearance of the annular rugae. Head provided with four hemispherical bothria and a central spheroidal, cup-like rostellum and with a bright red pigment streak on each side.

Measurements.—In the quiescent condition 0.5 to 0.625 mm. diameter, or 0.5 to 0.75 and 0.875 mm. long by 0.375 to 0.5 mm. broad, elongating without projection of the head to 1.125 mm. long, 0.375 mm. broad; with projected head to 1.5, 1.75, and 2.5 mm. long by 0.25 and 0.2 mm. broad. Bothria 0.15 diameter; central rostellum 0.1 mm. diameter.

The accompanying figures, 1, 2, 3, represent *Scolex picta* magnified forty diameters; figures 1, 2 in the quiescent condition, with the head retracted; figure 3 in the active condition, elongated and with the head protruded.

The *Scolex* when in motion, with the head retracted, elongates and shortens and narrows and widens proportionately. In contrac-

tion the posterior portion becomes more or less annularly constricted. In greatest activity the head is protruded and the body greatly elongated, and alternately shortens and elongates. With elongation the annular appearance of the posterior part entirely disappears. The rostellum and bothria are incessantly protruded and retracted and become more or less oval in form. In the quiescent state, by transmitted light, the head appears as a nearly central clearer spot embraced at the sides by the pigment streaks. When the bothria are protruded, the latter are situated posterior to them.

The body of the *Scolex* is filled with the usual oval, clear, sharply defined corpuscles. Under moderate pressure the water vascular system is brought into view. This appears as a tortuous vessel, proceeding forward on each side of the body from a little terminal caudal vesicle, returning from the head where it forms an expanded loop on each side of the rostellum.

With the *Scolex* as described there were found some smaller individuals having the same characters, but without the conspicuous pigment streak.

The *Scolex* of the Shad and Herring has a near resemblance to the *Scolex polymorphus*, Rudolphi, and it may, perhaps, prove to be the same. This species is described as having the bothria divided by a transverse partition, which is not the case in the *Scolex* under consideration. Van Beneden, however, represents forms of the *S. polymorphus* of the Turbot, without the division of the bothria (Mem. Acad. de Belgique, xxv, pl. 1, Figs. 1-3).

The mature tapeworm of the *Scolex* of the Shad and Herring is yet unknown and no doubt has for its host some animal that appreciates these fish for food quite as much as man does.

[May, 1888. No. 565. See Bibliography.]

Parasites of the Pickerel.—Dr. Leidy remarked that among the numerous parasites which are mentioned as infesting the Pike, *Esox lucius*, of Europe, no *Tenia* is indicated. In the Pickerel, *Esox reticulatus*, brought to our market, a species of the latter appears to be common. In two fishes he found half a dozen in the intestine and stomach; and in another a single individual two feet in length. It resembles closely the *Tenia ambloplitis*, noticed in the Rock Bass, *Ambloplitis rupestris* (Proc., 1887, 23), and may be the same. Distinguishing it with the name of *Tenia leptosoma*, its characters are as follows: Body long and thin, and at the forepart thread-like. Head unarmed, without rostellum, with four equidistant hemispherical bothria; neck very short or none; anterior segments

transversely linear, many times wider than long; posterior segments gradually becoming proportionately longer and quadrate and barrel shaped; genital apertures marginal, alternating irregularly. Ova spherical.

Length from 6 to 9 and 26 inches, shortening to one half or less; breadth to 2 and 2.5 mm. Head 0.25 to 0.5 mm. broad; bothria 0.125 to 0.175 mm. Anterior segments an inch from the head 0.175 mm. long by 1 mm. broad; posterior segments 0.5 to 0.75 mm. long by 2 to 2.5 mm. broad. Ova 0.028 to 0.032 mm. in diameter.

A single slender *Scolex* associated with the longest *Tenia* was 4 mm. long by 0.25 wide, but elongated to 8 mm. by 0.1 wide. The head was of the same form as that of the *Tenia*. After being in alcohol, the head of the *Scolex* was 0.225 mm. wide, with the bothria 0.1 in diameter. The posterior part of the body exhibited traces of segmentation, with the segments 0.075 mm. long by 0.25 wide.

[December, 1888. No. 568. See Bibliography.]

Food of Barnacles.—Prof. Leidy stated that last summer, in June, walking on the shore at Beach Haven, N. J., he picked up a bunch of Goose-barnacles, *Lepas fascicularis*, attached to a fragment of a grass-stem, *Spartina*. Finding at the time nothing else of interest, he examined the specimens, not having previously dissected a Barnacle since 1848, when he observed the eyes in *Balanus rugosus*. (See Proc., 1848, 9.)

All the specimens of *Lepas*, of which there were nine, had the body distended with a brownish-yellow Cyclops in large number, fresh in appearance and generally entire. Under the circumstances he at first suspected that they might be a larval form of the *Lepas*, though aware of the fact that the cirripeds proceed from a Nauplius embryo, which passes through a Cypris stage before assuming the Barnacle condition. On further investigation he was convinced that the Cyclops were food and filled the stomach. It appeared remarkable that they should have been so well preserved and not crushed by the strongly six-toothed mandibles of the Barnacle. Some additional specimens of this species and a few of *Lepas analifera* subsequently examined did not contain such an accumulation of similar food, but usually the contents of the stomach consisted from two to half a dozen small gastropods with the shell, several species of entomostraca, some sand grains, and a few vegetable fibers. In all the brood-capsule, a thin elliptical lamina, situated between the body and the shell, contained Nauplius larvae.

[November, 1888. No. 567. See Bibliography.]

Extract from Fauna of Beach Haven, N. J.—From an oyster bed we took up some young oysters, an inch to two inches long, with the shell perforated by the "drill," *Urosalpinx cinerea*. The perforation, made in the vicinity of the adductor muscle, about admits an ordinary bristle. An oyster-catcher, James R. Gale, informed us that the "drill" was introduced into the locality with spat brought from the coast of Virginia. With the *Urosalpinx* we took another snail, *Anachis similis*, which Mr. Gale assured us was more destructive, as a borer, to young oysters than the former. Another snail which we took, the *Euplicura caudata*, Mr. Gale says has the same habit.

Attached to oysters were also found a great profusion of the polypoon *Vesicularia dichotoma*.

The shrimp is infested to a wonderful degree with a parasitic crustacean, *Bopyrus palaeomonectola*.

[January, 1889. No. 571. See Bibliography.]

On Several Gregarines and a Singular Mode of Conjugation of One of Them.—Prof. Leidy communicated the following on some species of *Gregarina*: Among coleopterous insects the family of Tenebrionidae appears to be constantly infested with gregarine parasites. A remarkable species observed in one of our common beetles, *Nyctobates pennsylvanicus*, I propose to distinguish by the name of *Gregarina Philica*. The body is elongated clavate, variably thickened and rounded in front, somewhat tapering behind, and with the posterior end conical. Cephalic division campanulate, with the summit somewhat prolonged and surmounted by a horizontal circular disk with a rounded milled border. Conjugating individuals with the cephalic extremity conical and simple, or without the terminal disk. Length from 0.3 to 2 mm.; breadth 0.6 to 0.15 mm. (Drawing, etc.)

In conjugation the species is remarkable and, so far as I know, peculiar. In the pairing of most described species of *Gregarina*, two individuals, commonly of the same size, conjoin in the same line, the cephalic extremity of one attached to the caudal end of the other. In the species under consideration I have observed that the pairs conjoin, as represented in the accompanying figure, with the heads together and the bodies side by side. In numerous instances the position was invariable, and in all, the couples variably differed in size. Thus in one pair the longer individual was 1.75 mm. long and the smaller one 0.75 mm. long, and in another pair the larger individual was 2 mm. long and the other 1.75 mm. (Drawing.)

The species is pretty constantly found in the pro-ventriculus of *Nyctobates pennsylvanicus*.

Another interesting Gregarina is frequent in a common myriapod of our forests, the *Scolopocryptops sexspinosis*. It resembles the forms described by Kolliker as *G. Sieboldii* and by Siebold as *G. oligacantha*, referred by Stein to *Styloynchus*, and by Schneider to *Hoplorrhynchus*. These are common in Europe in the larva of a dragon-fly, *Calopteryx virgo*. The species under consideration I propose to name *Gregarina actinotus*. The body is elongated conical, thickest and rounded in advance and acute behind. The cephalic division is depressed spheroid and broader than long, and is surmounted by a long vase-like rostrum expanding at the top in a horizontal wheel-like disk divided at the border into short digitiform rays. Length from 0.06 to 0.52 mm.; breadth to 0.08 mm.; rostrum 0.08 to 0.1 mm. long. (Drawing.)

The accompanying figure represents the parasite. It is commonly found in considerable numbers, adherent by the rostrum to the inner surface of the proventriculus, looking like minute Echinorhynchi.

After finding the curious Gregarine of *Scolopocryptops*, one morning subsequently I found a fine *Cermatia forceps* in my bed-room. In it was another species which may be named *Gregarina megacephala*. The body is elongated ovate and acute or short clavate and obtuse with an unusually large ovoid and often constricted head, surmounted by a small rounded or elongated appendage. Length 0.42 to 0.75 mm. to 0.24 broad; head about one-fourth the length of the body. It approximates *Dufouria agilis* of Schneider, found in the larva of a *Hydracantharis*.

In some little green beetles, *Hoplocephala bicornis*, one of the Tenebrionidae, I found a number of gregarines remarkable for the small size of the head and hence the species may be named *Gregarina microcephala*. The body is clavate; the head like a watch crystal with a little ball at the summit. Length 0.35 mm. by 0.1 wide; head 0.012 long by 0.04 wide.

It bears a close resemblance to *Echinocephalus hispidus* of Schneider, found in *Lithobius forcipatus*, but in the one described I at no time found digitiform appendages to the head.

[No. 599. See Bibliography.]

[Gregarina. Dr. Leidy's unpublished manuscript upon the polycystid gregarines of the United States, which manuscript is in the possession of the Academy of Natural Sciences, Philadelphia, has been incorporated in an article by Crawley.*

* List of Polycystid Gregarines of the United States, H. Crawley, Proceed. Acad. Nat. Sci., Phila., 1903, p. 41.

In addition to ten new species described by Leidy, and already referred to, four more species are described and figured in the manuscript notes which appear in Mr. Crawley's original article, designated as follows:

Gregarina xylophini. Proc. Acad. Nat. Sci., 1903, p. 47.

Gregarina boletophagi. Proc. Acad. Nat. Sci., 1903, p. 47.

Euspora lucani. Proc. Acad. Nat. Sci., 1903, p. 50.

Astrophora cratoparis. Proc. Acad. Nat. Sci., 1903, p. 54.]

[April, 1889. No. 575. See Bibliography.]

A Parasitic Copepod.—Prof. Leidy remarked that last summer while at Beach Haven, N. J., there was brought to him from the surf a living specimen of the singular, transparent fish, *Leptocephalus*. In examining it he observed attached to the tail-fin a minute copepod crustacean, apparently of the genus *Chalimus*. The parasite was attached by a long filiform rostrum and resembled in this and other respects more the *Chalimus scomberi*, as represented by Baird, in Fig. 5, Tab. xxxiii, of the British Entomostraca, than it does the original of this species, as represented by Burmeister in the Nova Acta N. C. of Bonn, xvii, Tab. 23, Fig. 13. The species, which may be distinguished as *Chalimus tenuis*, is considerably less than half the size of *C. scomberi*. The cephalothorax, nearly twice the length of the breadth, is obovate and proportionately much narrower than in the latter species. The frontal segment is narrow and not prominent laterally, and the biarticulate antennæ are concealed beneath. The abdomen, half the length of the cephalothorax, exhibits three conspicuous divisions, and the short caudal appendages end in three minute setæ. Abdominal feet ending in biramous leaf-like segments fringed with short setæ. Rostrum linear and almost as long as the cephalothorax. Whole length 1.125 mm.; length of cephalothorax 0.5 mm.; breadth 0.275; length of rostrum 0.5 mm.; (?) length of abdomen 0.25 mm.

The accompanying outline represents the animal magnified forty-four diameters. (Drawing.)

[March, 1890. No. 585. See Bibliography.]

Hypoderas in the Little Blue Heron.—Prof. Leidy stated that Dr. B. H. Warren had submitted to his examination some pieces of the flesh, with areolar tissue and fat, from two individuals of the Little Blue Heron, *Florida caerulea*, through which were scattered a number of little egg-like bodies. These on examination proved to be a Mite of the genus *Hypoderas* of Nitsch, of which a dozen species

found as subcutaneous parasites in different birds have been described by Giebel (Zeitschrift gesam. Naturwiss., 1861, 438). The bodies in the Little Blue Heron were enclosed in connective tissue on the surface of the portions of muscles and elsewhere. They are white, elliptical, from 1.25 to 1.5 mm. long by 0.375 mm. broad, and are provided with four pairs of short, brown, bristly limbs. In other specimens submitted by Dr. Warren, consisting of the carcass and portions of the flesh of four individuals of the Blue-bird, *Sialia sialis*, similar egg-like bodies were found. They appeared to be embedded in the flesh among the muscular fibers. In the carcass they were scattered, especially on the back of the trunk, the neck, and the outside of the upper part of the thighs. They are white, elongated elliptical bodies from 1 to 2 mm. long, but without any external appendages. No distinct internal structure was observed. Though resembling to the naked eye the Hypoderas Mites, they are probably of a different nature, and perhaps may be psorosperms.

[September, 1890. No. 590. See Bibliography.]

Remarks on Ticks.—Prof. Leidy remarked that in his visit to Beach Haven, N. J., to spend the summer, he found the mosquito less numerous than usual, but in the earlier part of the season the Tick more frequent. One day in June, after passing for a few yards among some Myrica bushes, he picked eight of them from his clothes. They were repeatedly taken from a pet dog, but usually escaped notice until more or less filled with blood. Three in succession were unnoticed until fully distended and voluntarily detached themselves. One of these was weighed and found to be twelve grains. It was also found that it required nine unfed ticks to weigh one grain, so that the fed ones increased to more than one hundred times their weight and bulk. Curious to learn something of the life of the Tick, the three specimens were placed in a box in the beginning of July, in some moist sand and moss. They sought a slight hollow in the sand, from which they afterward did not move. After a week they began laying eggs, and this went on for a couple of weeks, until each Tick had extruded a mass nearly as large as itself. The eggs were laid in advance of the position of the body, discharged from between the anterior two pair of legs, the Ticks remaining constantly in contact with them. The eggs were oval, brown, and shining and measured 0.5 mm. long. The parents became much contracted and shriveled and all died from the 16th to the 18th of August, about the time the eggs began to hatch. This continued for about a week, until all were hatched.

The larval Ticks were brown, ovate, and possessed three pairs of limbs. They measured 0.6 mm. long and 0.4 mm. broad. As many escaped between the side of the lid and the box in which they were contained, they were transferred into a glass bottle with a cork stopper about an inch broad. The ticks gradually collected into three compact swarms, the largest of which was formed beneath the cork its whole breadth and sometimes, in part at least, nearly a line thick. Another swarm compacted itself in the interval of two crossing twigs about as long and thick as the little finger, and the third formed a dome-like mass about one-third of an inch broad, on one of the twigs. From time to time they partially scattered, and then collected again in the same close swarms.

Exhibited to the Academy this evening, September 23, the young Ticks appear yet to be alive and in good condition, though they have eaten nothing. Fruit and other parts of plants have been placed at their service, but they do not even approach them. On two occasions some were placed on Prof. Leidy's arm, but they did not seem disposed to attach themselves.

The mature Ticks present two well marked varieties, probably the two sexes. In the one there is a conspicuous white spot on the back immediately behind the head, sharply defining a thoracic shield. In the other there is no distinct appearance of the shield, but fainter white streaks lie outside of its position and extend in four feebler streaks on the abdomen, apparently defining the intestinal cœca. In the former the genital aperture is central between the anterior two pair of limbs; in the latter it is between the second pair of limbs. The blood-filled specimens that laid the eggs accord with the former.

He was unable with certainty to refer our common Tick to its proper place among the multitude that have been named, but supposed it to be the *Amblyomma americanum* of Koch, indicated earlier by Linnaeus as *Acarus americanus*. There is much uncertainty in the knowledge of our Ticks. Koch ascribes nine species to North America, referring them to the genera *Amblyomma*, *Ixodes*, and *Dermacentor*, the last belonging to Pennsylvania. Say describes six other species of *Ixodes*, Packard two, and Riley one. Say's *Ixodes scapularis*, which the author says is common in our forests and attaches itself to various animals, seems to approach closely the Beach Haven Tick, and Riley's *Ixodes bovis* also seems to accord pretty well, judging from the figures and characters given. If, however, the latter at maturity is half an inch long, as stated by Packard, it is most probably a different species from the *Amblyomma americanum*.

num. He had in his possession a Tick, distended with blood, half an inch in length, which came from Camp Sheridan, Nebraska, agreeing in all respects with those from Beach Haven.

Amblyomma differs from *Ixodes* in the possession of eyes, and he was by no means satisfied that the Beach Haven Ticks possess such organs, unless they form the prominent posterior angles of the head. The Ticks have been supposed to feed on vegetable matter until they reach maturity. As the mouth organs of the larva do not differ from those of the adult, he thought this doubtful.

In the American Entomologist, 1870, p. 160, Seed-Ticks found under the bark of apple trees are stated to be the young of one of our most common Wood-Ticks, *Ixodes unipunctata*, but he thought this has not been positively determined to be the case.

He had been repeatedly told of a minute tick, commonly called the Seed-Tick, not uncommon in our vicinity, which attacks man and buries itself beneath the skin. He had suspected it to be the young of *Ixodes*, but had no opportunity of determining the question.

NOTE.—The following day, September 24, the young Ticks appeared generally less active, and many were motionless and seemed dead. Thirty active ones were placed on the inside of his fore-arm, and there remained for ten minutes, but as they wandered about aimlessly and with no apparent disposition to attach themselves, they were removed.

Though the young Ticks had not fed, they actually seem to have grown, for at the present time they generally measure 0.725 mm. in length by 0.45 mm. in breadth.

The adult male and female appear about the same size, for the two range from 1-8th to 3-16ths of an inch in length. One of those distended with blood measured 9-16ths of an inch long by 6-16ths in breadth, and similar specimens after having laid their eggs had shrunken to 7-16ths by 5-16ths.

Finally the same day the Ticks were placed in alcohol for preservation.

[September, 1890. No. 591. See Bibliography.]

Parasites of Mola rotunda.—Prof. Leidy stated that one day during his stay at Beach Haven, N. J., while men of the life-saving station were directly off shore watching the bathers in case of accident, a Sun fish, *Mola rotunda*, approached the boat, apparently, as they supposed, sleeping. The fish, weighing nearly two hundred pounds, was readily taken without resistance. It proved to be of additional interest from the great number and variety of parasites with which

it was infested. Some of these had occasioned a considerable degree of ulceration along the base of the caudal fin. Chief among them was the large Lernea, *Penella filosa*, which hung in great clusters from the root of the dorsal and other fins. They were from five to seven inches long, and had the head and neck buried in the flesh of the fish from one to three inches. To many of them were appended the curious barnacle, *Conchoderma virgata*; on one *Penella* a bunch of seven, most of which were nearly two inches long. Were also more or less profusely covered with colonies of the Hydroid Polyp, *Eucope parasitica*.

The characters of the *Penella* are as follows: Head compressed spheroid, ventrally thickly papillate, dorsally with a median and lateral pair of obtuse horns. Neck long and cylindrical, with 4 pairs of minute black hooks just behind the head ventrally. Thorax thicker, cylindrical, annulated. Abdomen or tail shorter, narrower and annulated, with crowded lateral filamentary appendages branching from the base. Ovaries long and filiform. Head, neck, and ovaries straw-colored; thorax, abdomen, and appendages black.

In the Règne Animal of Cuvier, it says, there is in the Mediterranean a species, *Penella filosa*, seven or eight inches long, which penetrates into the flesh of the Sword-fish, the Tunny, and the Sun-fish, and torments them horribly. Similar cases of the wonderful bounty of nature are frequent, and remind us of the remarks of Mr. Spencer, considered more favorable to the evolutionary than to the special creation theory. While to both may be applied the question, why the amount of suffering entailed on sentient beings by parasites could not have been avoided, to the former there does not arise the question, why are they deliberately inflicted?

Of other crustacean parasites of the Sun-fish there were three. Of these one, *Cecrops Latreillii*, Leach, was attached to the gills. Six mature females were about an inch in length, and three of them had the male appended, about half the length, and had well-stocked ovaries. Three additional young females were 14 mm. long.

The other two species were attached to ulcerated surfaces at the root of the caudal fin. One of them, *Læmargus muricatus* Kroyer, of which there were four females, were from 15 to 18 mm. long.

The remaining species, nearly resembling *Læmargus*, seems to be the *Dinematura serrata* Kroyer, of which there were three females from 6 to 7 mm. long.

Gliding on the skin, at the sides of the body of the fish, was the circular Fluke-worm, *Tristomum Rudolphianum*, of which four ranged from 16 to 20 mm. in breadth.

In the intestine was another apparently undescribed Fluke-worm, which may be named *Distomum pedocotyle*. Of three individuals one was 20 mm. long by 0.5 mm. thick; the others were 40 to 45 mm. long and 1.5 mm. thick. The body is cylindrical, narrowest at the fore part and obtuse behind, with the ventral bothria larger than the mouth and projecting in advance to an extent equal to the body: with the skin smooth and transparent, the yellow intestine and the white and brown genitals shining through.

The soft, yellow liver was throughout pervaded with a cestoid worm, *Anthocephalus elongatus* Rudolphi. The organ looked like a bundle of tangled cotton cord packed in the hepatic substance. The larger worms were probably upward of several feet in length, but with much effort about a foot and a half of only one individual was disengaged from the liver. In the larger specimens the cystic envelope of the cephalic end appears as a vesicle from a fourth to half an inch in diameter. When disengaged, the cephalic extremity appears as a sausage-shaped expansion, from three-fourths to an inch long, within which was the inverted head and neck from half to three-fourths of an inch long. The head, provided with a pair of lateral oblique bothria, enclosed four thread-like proboscides armed with numerous recurved hooks.

[November, 1890. No. 593 See Bibliography.]

NOTICES OF ENTOZOA.

1. *Ascaris lumbricoides*, Linné.
2. *Trichocephalus dispar*, Rudolphi.
3. ? *Filaria primana*, n. s.

In the dissection of an Orang, *Simia satyrus*, which died in our Zoölogical Garden, Dr. H. C. Chapman found in the intestines several worms (Proc. 1880, 166), which were submitted to my examination. Three seem in no respect to differ from the ordinary *Ascaris lumbricoides*, one of the specimens being 18 centimeters long. One from the cæcum seems to be *Trichoccephalus dispar*. The occurrence of these parasites of man in a near relative outside the genus is an interesting fact.

Three other worms are unknown to me and I am in doubt as to their generic character. They are females, and measure up to 26 centimeters long by 2.75 millimeters thick. They are more robust than species of *Filaria* commonly are, and in this respect are more like *Eustrongylus gigas*. Although neither of these usually live in the intestine, I provisionally refer the worms to the former genus. The body is nearly uniformly cylindrical, being 2.5 mm. thick, one

centimeter back of the cephalic end, gradually increasing to 2.75 mm., and behind slightly tapering to 2 mm., one centimeter from the tail end. The head is rounded conical, with the mouth as a central pore enclosing a minute papilla and unarmed. The tail is blunt conical. An anal aperture was not detected, but the genital aperture appears near the cephalis end. The species may be distinguished as *Filaria primana*.

4. *Ascaris Osculata*, Rudolphi.—Body cylindroid, tapering in advance; mouth with prominent lips; caudal end incurved; tail short, as wide as long, conical, obtuse.

Ten females from 25 mm. long and 1 mm. thick to 60 mm. long by 2 mm. thick.

From the Elephant Seal, *Macrorhinus angustirostris*, which died at the Zoölogical Garden. Submitted by Dr. Chapman.

5. *Ascaris transfuga*, Rudolphi.—Body cylindrical, moderately and nearly equally tapering at both ends; head with narrow lateral alæ and prominent lips.

A female 6 inches long and a male 4 inches.

From the Polar Bear, *Ursus maritimus*, of the Zoölogical Garden. Submitted by Dr. Chapman.

6. *Ascaris simplex*, Rudolphi.—Body cylindrical, tail short, conical, straight, with a minute muero.

One female 4 inches long by 1.5 mm. thick; a multitude of young with no males, generally from 20 to 50 mm. long by 0.3 to 0.5 mm. thick.

From the stomach of *Mesoplodon sowerbiensis*. Submitted by Dr. Cooper Curtice, Washington.

7. *Ascaris spiculigera*, Rudolphi.—Females to 45 mm. long by 2 mm. thick; tail short, acute. Males 30 mm. long by 1 mm. thick; tail short, incurved, acute. A pair of curved spicules exserted from the genital aperture.

Numerous specimens from the stomach of *Pelicanus fuscus*, Florida. Submitted by Mr. F. C. Baker.

8. *Ascaris diacis*, n. s.—Body cylindrical, spirally rolled, pinkish-white, translucent, with the brown intestine shining through, smooth, about equally tapering at the ends. Head without appendages; mouth trilobed, with lobes large and rounded. Tail straight, conical, acute, without papillæ.

A female 70 mm. long by 1.25 mm. thick. Obtained by Dr. B. H. Warren from the body cavity, in the vicinity of the cloaca of the Purple Grackle, *Quiscalus quiscale*, Chester county. Submitted by Dr. Warren.

9. *Actractis (Ascaris) opeatura*, n. s.—Body fusiform, most tapering and subulate behind; head rounded and tripapillate. Female broader; tail long, straight, acute, without appendages; vulva slightly tumid, situated a short distance in advance of the anus. Tail of male shorter, incurved, with a mucronate point about one-third its length, with two pairs of tubercles ventrally near the middle and a pair opposite dorsally. Genital spicules curved; one twice the length of the other.

Œsophagus cylindrical, bounded by chitinous rods; pharynx about as long, slightly narrower and expanded below; intestine dilated at commencement, but quickly narrowing; rectum short.

Length of females to 5 mm. by 0.33 mm. thick at the middle; tail 7 mm. long. Length of males nearly as in the former by 0.2 mm. thick; tail 0.375 mm. long. About an ounce measure of the worms obtained from the intestine of an Iguana, *Cyclura bacolopha*, Cope, from the island of New Providence.

10. *Trichoccephalus affinis*, Rudolphi.—About a pint measure of this worm was taken from the large intestine of a camel, *Camelus bactrianus*, which died at the Zoölogical Garden and was dissected at the Biological department of the University, in the museum of which the worms are preserved.

11. *Filaria horrida*, Diesing.—A dozen females and as many males were taken from the body cavity of an American Ostrich, *Rhea americana*, from the Zoölogical Garden, dissected at the Biological department of the University; preserved in the museum.

12. *Filaria obtusa*, Rudolphi.—Body pinkish-white, cylindrical; cephalis end rounded, smooth; caudal end obtuse. About a dozen specimens, female and male, from the abdominal cavity of the Barn Swallow, *Chelidon erythrogaster*. Obtained by Dr. B. H. Warren, Chester county.

The mouth organs consist of a pair of trilobate, elongated clavate appendages. Dujardin figures them as conjoined in loops. Length of the organs 0.12 mm. long. Spicules of penis 0.75 mm. long. Ova 0.04 mm. long, 0.032 mm. broad.

13. *Cheilospirura uncinipenis*, Diesing.—*Spiroptera uncinipenis*, Molin.—Body cylindrical, nearly equally tapering at the extremities; head naked. Caudal extremity of the female obtuse; of the male spiral, alate; alæ longitudinally corrugated. Penis long, curved, and acuminate; sheath hooked at the extremity narrowly bialate.

Several dozen from the gizzard of the *Rhea americana*. Collection of the Biological department of the University. Females 25 to 32 mm. long; males 20 mm. long.

14. *Physaloptera retusa*, Rudolphi.—Body cylindrical, most tapering in advance; mouth retractile, with six papillæ; caudal end acute; in the male bialate, with the alæ supported by four ribs. Four males from 10 to 12 mm. long and a female 24 mm. long from the intestine of *Varanus?* Submitted by Dr. H. C. Chapman.

15. *Trichosomum? tenuissimum*, n. s.—In a mature male Brown Rat, *Mus decumanus*, embedded in the liver, were a number of irregular milk-white bodies, some appearing as spots and others as interrupted lines. These proved to be exceedingly slender thread worms, more or less coiled up in the substance of the liver. They were so delicate that I failed to detach one of them entire. One specimen teased out, but broken into half a dozen pieces, was estimated to be two inches long and was only one-tenth of a millimeter thick. The anterior extremity is much attenuated, with the head acuminate; the posterior extremity thicker, straight, and without papillæ. Mouth minutely papillate, unarmed. Tail very short, blunt conical. Generative aperture at the fore part of the body and conspicuously swollen. The specimen, a female, contained numerous immature eggs. In some fragments of another worm a third of a millimeter thick the uterus was distended with mature eggs. These are white, oval, 0.04 mm. long and 0.032 mm. broad. They have a thick striated shell, with a cylindrical aperture at both poles.

16. *Echinorhynchus pellucidus*, Leuckart.—Body cylindrical, slightly wider at the extremities; anterior extremity barrel-shaped and armed with two zones of short, conical, recurved spines; posterior extremity obtusely rounded. Proboscis clavate, with extremity oval and armed with about a dozen rows of strong hooks; neck conical, smooth.

A dozen females, attached to the lining membrane of the intestine of *Mesoplodon sowerbiensis*, ranging from 10 to 18 mm. long by 0.6 to 1 mm. broad. Submitted by Dr. Cooper Curtice, Washington.

17. *Echinorhynchus paucihamatus*, n. s.—Body cylindroid, widest in front and tapering behind, annularly constricted, truncate at the caudal end. Proboscis cylindrical, about three times the length of the thickness, clavate at the extremity and furnished with a single row of six large abruptly bent hooks, succeeded by two rows of small ones about half the length of the former. Length 4 to 12 mm.; thickness at the fore part 0.5 mm.; behind 0.25 mm.; proboscis 0.5 mm. long; large hooks 0.625 mm.

Frequent and abundant in the small intestine of the Black Bass, *Micropterus nigricans*; usually found loose and with the proboscis retracted.

18. *Amphistomum fabaceum*, Diesing.—Body hemiovoid, convex dorsally, flat ventrally. Numerous specimens, from 7 to 9 mm. long by 3.4 to 5 mm. broad, from the large intestine of a Sea-cow, *Manatus latirostris*, which died in the Zoological Garden in 1875. Submitted by Dr. H. C. Chapman. Numerous specimens, many of larger size, up to 11 mm. long by 9 mm. broad, were obtained from the nasal passages of another Sea-cow, and were presented to the Academy by Jacob Geismar.

19. *Distomum trapezium*, n. s.—Body ovate lanceolate, flat, smooth, narrowest in front; mouth subterminal, transverse oval, unarmed; ventral acetabulum situated a short distance behind the former, about twice the size. Color brown, darker laterally and thicker, due to the vitelline glands, which extend from the ventral disk to the posterior extremity of the body. Testes just behind the ventral disk; uterus dendritic and occupying the interspaces of the vitelline glands. Genital aperture back of the oral disk. Length 21 mm., breadth 6 mm. A single specimen from the American osprey, *Pandion carolinensis*. Submitted by Dr. H. C. Chapman.

20. *Distomum aniarum*, n. s.—Body elliptical, flat, translucent white with a median brown streak, smooth. Oral acetabulum sub-terminal, circular; mouth transverse oval, unarmed. Ventral acetabulum larger, sessile, situated just in advance of the middle of the body. Genital aperture close to the oral acetabulum; uterus median, tortuous, filled with brown ova; testes two, situated one on each side immediately behind the ventral acetabulum. Length from 1.875 to 3 mm.; breadth 0.875 mm. to 1 mm.; diameter of oral acetabulum 0.375 mm.; of ventral acetabulum 0.5 mm. Ova oval yellowish-brown, 0.032 by 0.02 mm. Six specimens obtained from the mouth of the Water-snake, *Tropidonotus sipedon*. Submitted by Dr. H. C. Chapman.

21. *Distomum incommodum*.

? *Monostomum incommodum*, Leidy. Pr. A. N. S., 1858, 43.

Distoma oricola, Leidy, Ibid., 1884, 47.

22. *Distomum gastrocolum*, n. s.—Body elongated, elliptical, flattened, smooth, translucent reddish, with brown intestine and yellowish genitals; cephalic extremity narrower, posterior extremity obtusely rounded, or somewhat abruptly prolonged and truncate and with a large contractile vesicle opening externally; ventral acetabulum spherical, nearly as broad as the body; oral acetabulum about half the size of the former. Pharynx immediately succeeding; forks of the intestine capacious, distant from the end of the body. Uterus coiled along the middle of the body and filled with yellowish ova;

testicles paired, spherical, situated behind the ventral acetabulum; genital apertures behind the oral acetabulum. Length from 2 to 3 mm. by 0.5 to 0.75 mm.; in movement elongated to twice the length and most narrowed in advance of the ventral disk; the latter to 0.5 mm. Ova 0.02 by 0.016 mm.

Several hundred attached to the lining of the stomach from its commencement to the end of its caecal extremity. From the Skipjack, *Trichiurus lepturus*.

23. *Distomum ischnum*, n. s.—Body long, narrow, band-like with the ventral disk at the anterior fourth: smooth, translucent, brownish with lateral black lines due to the long, tortuous, and sacculated forks of the intestine: anterior extremity slightly narrower, with rounded head and unarmed: posterior extremity transversely corrugated, with parallel sides and rounded truncate, emarginate end; ventral disk about half the width of the body: oral disk smaller; uterus coiled along the middle of the body and distended with ova. Length 8 mm. by 0.875 mm. wide; ventral disk 0.625 mm. Ova 0.02 by 0.012 mm.

A dozen specimens from the mouth, throat, and gills of the Sand-pike, *Saurus fuscus*. Beach Haven, N. J.

24. *Distomum lasium*, n. s.—Larval form. Body fusiform, widest at the ventral disk, which is situated near or a little in advance of the middle, finely annulated and minutely echinate: anterior extremity wider, rounded at the end: posterior extremity moderately tapering, truncate and emarginate at the end. Ventral disk large: oral disk nearly as large, with a style inserted in the upper lip. Interior organs, except the posterior contractile sac of the vascular system, indistinct. Sporocyst simple, elliptical with from few to numerous larval distomas.

Larva 0.2 to 0.33 mm. long by 0.08 to 0.1 mm. wide; elongating to 0.4 long by 0.04 mm. wide. Oral disk 0.048 mm.; ventral disk 0.06 mm.; style 0.016 mm. Sporocyst 0.375 by 0.15 mm. to 0.875 by 0.25 mm.

Very common and numerous in the liver of *Ilyanassa obsoleta*, Beach Haven, N. J. *Ilyanassa* occurs in great abundance at Beach Haven, the mud flats of the neighboring sounds, at low tide, being covered in dense patches. Covered with dirt, the ordinary observer takes them for pebbles. In dissecting a number I found that about one in five or six was infested with the larval distomas enclosed in sporocysts, often in large numbers, embedded in the liver and associated genital gland. The larvae always appear in the distoma form and never as a cercaria. They exhibit no trace of genital organs.

and were all provided with a conspicuous style, in the forehead as it were, ready for penetration into their as yet unknown future host.

25. *Distomum centraappendiculatum*.—*Distoma appendiculata* Leidy. Proc. A. N. S., 1877, 202: not *Distomum appendiculatum* Rudolphi.

26. *Tetracotyle tipica*, Diesing.—Body flattened obpyriform, with an oral, a ventral central and anterior lateral pair of bothria. Length 1.125 to 1.25 mm. long by 0.95 to 1.125 mm. broad.

Encysted in the liver and genital gland of *Lymnaea catascopium* and *Physa heterostropha*. Sixty-five specimens were obtained from a single Physa.

27. *Cercaria platyura*, n. s.—Body elongated hemielliptical, widest and truncate behind; head rounded; oral acetabulum large and spherical, with a strong style in the upper lip; ventral acetabulum central, smaller than the former. Tail nearly as long as the body, stout, tapering, corrugated, and with a broad, costate, lateral membrane. Length 0.8 mm.; body 0.4 by 0.12 mm.; tail 0.36 by 0.06 mm. at base, breadth with membranous alæ 0.14 mm.; oral acetabulum 0.08 mm.; ventral acetabulum 0.06 mm.

Found free in a pool, with *Lymnaea*, at Fort Bridger, Wyoming.

28. *Cysticercus tenuicollis*, Rudolphi. The larva of *Tænia marginata* Batsch.

1. A specimen enclosed in a spherical cyst an inch in diameter attached to the paunch of a young sheep, *Ovis aries*. *Cysticercus* 3 inches long with terminal cyst an inch in diameter; the retracted head and neck an additional inch in length. Submitted by Dr. J. Cheston Morris.

2. A specimen from the vagina of a Sheep measured $5\frac{1}{2}$ inches in length, with the terminal cyst over an inch in diameter.

3. A specimen enclosed in a sac an inch in diameter attached by a pedicle two inches in length to the liver of a Monkey, *Semnopithecus entellus*. The worm was 22 mm. long; the body 8 mm.; the terminal cyst 14 mm. in diameter; the retracted head 1 mm. broad; the bothria 0.375 mm.; the rostrum with its double circle of hooks 0.375 mm. Submitted by Dr. H. C. Chapman.

29. *Cysticercus pisiformis*, Zeder.=Larva of *Tænia serrata*, Goeze.—Numerous saes simple and compound, ranging from 2 to 3 centimeters in diameter, with worms isolated and in groups in various stages of development. One large sac contained a dozen groups adherent to the inner surface; the groups with from 6 to 30 worms, opaque yellowish, obconic from 4 to 6 mm. long by 1.5 mm. thick, with head and neck retracted nearly the length of the rest of the body, which is transversely corrugated. Bothria 0.225 mm.; ros-

trum 0.3 mm. broad; upper hooks 0.14 mm. long, lower ones 0.1 mm. long.

From the peritoneal cavity of the Jack Rabbit, *Lepus palustris*, from northern Minnesota. Submitted by Mr. Horatio C. Wood.

30. *Tænia nematosoma*, n. s.—Head rounded quadrate, unarmed, with equidistant hemispherical bothria and a small central papilla; neck short or none; fore part of body linear; anterior segments much wider than long; posterior segments gradually becoming proportionately longer, quadrate or barrel-shaped; genital apertures marginal and alternating irregularly. Length to 9 inches, contracting to about one-half. Breadth of head 0.375 to 0.5 mm.; bothria 0.175 wide; neck 0.25 wide; anterior segment an inch from the head 0.175 mm. long by 2 mm. broad; posterior segments 0.75 mm. long by 2 mm. broad, and when contracted widening to 2.5 mm. Ova spherical, 0.028 to 0.032 mm.

A half dozen specimens in the stomach of two Pickerel, *Esox reticulatus*.

31. *Tetrabothrium triangulare*, Diesing?—Head large, oblate, spheroidal, and formed by four large bothria; neck short or none; anterior segments of the body transverse linear, then oblong square, the posterior segments short campanulate; genital apertures marginal.

Several inches in length; described from fragments of several individuals. Head 0.55 mm. long by 0.75 mm. broad; bothria 0.5; neck 0.3 wide; body 15 mm. behind the head indistinctly segmented and 0.125 mm. wide. In a fragment without the head, about an inch long, the anterior segments are oblong square with prominent marginal genital apertures and 0.3 mm. long by 0.25 mm. wide; the posterior segments 0.175 mm. long and 0.2 mm. wide. In a posterior segment of half an inch the segments readily separable are short campanulate, 0.175 mm. long and 0.375 mm. wide. From the intestine of *Mesoplodon sowerbiensis*. Submitted by Dr. Cooper Curtice, Washington.

32. *Tetrabothrium loliginis*.

Tænia loliginis, Leidy. Proc. A. N. S., 1887, 24.

The Scolex of *Tetrabothrium Rudolphi*, or *Phyllobothrium* Van Beneden. A dozen specimens in alcohol, obtained from the Squid, *Ommastrephes illecebrosa*, at Bar Harbor, Me. In their present condition they are an inch in length or less and from 2 to 3 mm. wide, linear lanceolate, posteriorly acute and unsegmented. The head is prominent, spheroidal, and consists of four much-folded rosette-like lobes with hemispherical bothria. Submitted by Dr. H. C. Chapman.

33. *Phyllobothrium inchoatum*, n. s.—Ten specimens, taken from the blubber in the vicinity of the vent of *Mesoplodon sowerbiensis*, preserved in alcohol, appear as depressed fusiform bodies from 14 to 18 mm. long and 3 or 4 mm. broad. The retracted head is globose quadrate, and is provided with four larger globose and plicated bothria. Submitted by Dr. Cooper Curtice, Washington.

34. *Pentastomum proboscideum*, Rudolphi.—Cylindrical, slightly narrowing behind and ending obtusely; head marked by a constriction, spherical, fore and aft flattened and wider than the body.

Two females 100 mm. long, with the head 5 mm. broad and the body 3 mm. A male 35 mm. long, the head 4 mm. broad and the body 2.5 mm., marked with about 48 rings. In the females the fore part of the body is distinctly annulated, but indistinctly behind. From the lung of a Black Snake, *Coluber constrictor*, Florida. Submitted by Mr. F. C. Baker.

A male *Pentastomum*, obtained by the same gentleman from a Skunk, *Mephitis mephitica*, is like the one above indicated. It is 30 mm. long and distinctly annulated, with about forty-eight rings. The head is cap-like, orbicular, convex dorsally and concave ventrally.

[November, 1890. No. 594. See Bibliography.]

Remarks on Velella.—Prof. Leidy exhibited specimens of *Velella mutica*, which, with many others, were cast on shore at Beach Haven, N. J., in the early part of last August. The living ones were of a deep blue color, and ranged from an inch and a half to three inches in the greater breadth. From them there were detached multitudes of Gonophores, minute jelly fishes, measuring 0.44 mm. long by 0.32 mm. broad.

[April, 1891. No. 597. See Bibliography.]

NOTICE OF SOME ENTOZOA.

Distoma crassum, Busk. Cobbold: Proc. Linn. Soc., 1860, vol. V, p. 5.

Mr. Busk, an English surgeon, in 1843 announced the occurrence in the intestine of a Lascar or Hindoo seaman, who died in London, of a large species of Fluke, for which he suggested the name of *Distoma crassum*. Fourteen specimens obtained ranged from 4 to 6 cm. long by 1.7 to 2 cm. broad. The same parasite has since been reported as occurring in Chinese and in Europeans living in China.

(Cobbold, Parasites, 1879, 21.) In our Proceedings for 1873, p. 304. I gave notice of a specimen from a Chinese boy, which I then supposed to be a larger individual than usual of the more common *D. hepaticum*.

On several occasions I have had the opportunity of examining some large Flukes from the liver of our Deer, *Cervus virginianus*, and the Domestic Ox, which appear to be identical with the *D. crassum*. The specimens preserved in alcohol and submitted to me are as follows :

Six individuals, obtained from the liver of a Doe, in the Adirondack Mountains of New York, by Dr. R. A. F. Penrose. These range from 5 to 6 cm. long by 1.5 to 2.5 cm. broad and 1.5 to 2.5 mm. thick.

Three individuals from the liver of a Calf at Hot Springs, Ark., obtained by Dr. G. W. Lawrence. The specimens much contracted and hardened by strong alcohol measure 3.5 cm. long by 2 to 2.4 cm. broad. An imperfect one is from 3 to 4 mm. thick at the broken border; white for half the thickness dorsally and black ventrally.

Two individuals recently received from Texas from Dr. M. Francis, veterinary surgeon, who writes that the monster Flukes occur there in cattle in limited number in the liver-tissue and not in the bile-duets like the *Distoma hepaticum*. The specimens measure 3.5 and 4 cm. long by 2 and 2.5 cm. broad.

The Flukes from all three hosts accord in character except size, and in many points appear closely related with the *D. hepaticum*. They are elliptical in outline and of greater proportionate breadth than in the latter. The oral pole is conical, but not abruptly prolonged as in that species. The caudal pole is broadly rounded and entire or medially slightly emarginate. The dorsal surface is convex, smooth, and cream-colored; the ventral surface flat or slightly concave, minutely granulate or brownish margined with black, due to the vitelline organs shining through. The oral and ventral acetabula are from 4 to 5 mm. apart; the former oral about 1.5 mm. wide; the latter slightly larger. Genital aperture midway between the acetabula. Penis in some individuals exserted as a short tortuous papilla. The sides of the body extending from near the head to the tail, occupied by intensely black dendritic vitelline organs. The body is less tenacious than in *D. hepaticum*, is soft and easily broken.

Accompanying the monster Flukes from Texas were eighteen specimens of the ordinary Liver-Fluke, *Distoma hepaticum*, up to

3.5 cm. long by 9 mm. broad, which Dr. Francis observes are very destructive to Cattle and Sheep in some parts of Texas.

The facts related of the recent occurrence of the large Fluke in the Deer and Ox in different portions of the United States would impress one with the idea that the parasite is common with us, but in view of its conspicuous character and its not having been previously noticed such is probably not the case. May there be any relation between the occurrence of the parasite in this country and the influx of a Chinese population? The facts seem curiously coincidental with the first discovery of *Trichina* in man in England and its subsequent discovery in the Hog in this country. The Guinea-worm is believed to have been introduced into tropical America with the Negro from Africa.

Sclerostomum armatum Rudolphi, var. *major* Diesing; Syst. Helm., II, 304.

Dr. Edward Landis recently submitted to my examination three worms found coiled in as many thick-walled cysts, in the lung of a horse. These appear to me to be the larger variety of the *Sclerostomum armatum*, usually found occupying the intestines of the same animal. The specimens, all females, are from 25 to 30 mm. long by 1.5 mm. thick at the fore part. The body is robust, cylindrical, more tapering behind, brownish-red, annularly striated; head dome-like, defined by an annular stria; mouth large, surrounded by a prominent annular lip marked by eight radii; tail short, conical, obtuse.

Ascaris anoura Dujardin: Hist. Nat. des Helminthes, 1845, 221. Leidy: Proc. A. N. S., 1856, 51.

Ascaris attenuata Molin: Faunæ Helminth. Venetæ, 1860, 282.

Ascaris rubicunda Schnyder: Monog. T. Nematodon, 1866, 42.

From the stomach of a Python, *P. molurus*, which recently died in our Zoölogical Garden, Dr. John L. Hatch obtained a large mass of translucent red and green worms, which were submitted to my examination. These appear to be the *Ascaris anoura* of Dujardin, subsequently described under other names by Molin and Schnyder. The worms for the most part penetrated the recesses of three larger tumefactions of the mucous membrane of the stomach. The greater number of the worms were immature, translucent, of a blood-red color, with a darker intestine shining through, and ranging from 6 to 7 cm. long by about 0.6 mm. thick. The mature females ranged from 10 to 20 cm. long by 1.5 to 2.5 mm. thick. The males ranged from 7 to 16 cm. long by 0.875 to 2 mm. thick.

The body of the worms was most narrowed in advance, from pale red to nearly colorless in the largest and deeper to blood red in the smaller ones; with the intestine shining through of variable pea green to greenish-brown and dark brown in the latter, and with the tortuous ovaries and testes milk white. Cephalic extremity lighter colored, strongly tapering and with distinctly trilobate mouth. Tail very short, conical, the length about equal the breadth at base. The male of more slender proportions, with the caudal end incurved and the tail more pointed, with a row on each side of ten preanal papillæ, one on each side of the anus and two rows of two on each side of the tail. Spicules of the penis long, linear, curved and equal. Pharynx long, cylindrical clavate; rectum very short.

Worms closely agreeing with those of the Python I have observed from two of our common snakes, the Hog-nose Snake, *Heterodon platyrhinus*, and the other, from the accompanying description, supposed to be the Milk-snake, *Ophibolus triangulus*. A portion of the stomach of the latter, preserved with the worms, shows them to have the same habits as those of the Python; partially occupying the recesses of the tunefaction of the mucous membrane.

[No. 99. See Bibliography.]

ON THE ORGANIZATION OF THE GENUS GREGARINA OF DUFOUR— CHARACTER OF THE GENUS.*

1. *Gregarina Juli Marginati.*

Gregarina larvata, Leidy. Proc. A. N. S., vol. iv, p. 232.

2. *Gregarina Juli Pusilli*.—White, translucent, oval. Cephalic sac hexahedral, with the sides rounded or forming a double cone base to base, with the upper apex subacute or truncated in younger individuals. Posterior sac robust, oval; granular contents fine, translucent; interior corpuscle globular, transparent; nucleus transparent, without nucleolus. Whole length from the 1-1500th inch to the 1-275th inch. Breadth of largest the 1-500th inch. Diameter of head of largest 1-1500th inch.

Habitation.—Intestine of *Julus pusillus*.

Movements.—Its movements are not frequent.

3. *Gregarina Polydesmi Virginiana*.—White, translucent, clavate or oval. Cephalic sac campanulate, globular, or prolate, or oblate spheriod, surmounted by a papillary thickening of the integument; interior granular mass very fine and translucent. Pos-

* Transactions American Philosophical Society, 1851.

terior sac globular, oval, clavate, spatulate, fusiform, or urceolate; posteriorly obtuse; parietal integument wrinkled or distended; granular contents very fine, faint, translucent; corpuscles, one or two, globular, transparent, very faintly granular. Whole length from the 1-1000th inch to the 1-28th inch. Breadth from the 1-1000th to the 1-430th inch. Cephalic sac in largest 1-1400th inch long. Corpuscle 1-3000th inch to the 1-1000th inch in diameter.

Habitation.—Intestine of *Polydesmus virginicus*.

Movements.—Moderate and slow.

4. *Gregarina Passali Cornuti*.—White, opaque, in pairs, wrinkled. Cephalic sac hemispherical, without papillary thickening of the integument; interior granular mass opaque. Posterior sac flaccid, when distended subglobular; granular contents opaque white, completely obscuring the interior corpuscle. Average length in pair, after distension, 1-66th inch; breadth the 1-133d inch. Cephalic sac 1-260th inch at base; projects from body cell 1-533d inch. Muscular lines of the posterior sac 1-25000th inch apart.

Habitation.—Proventriculus of *Passalus cornutus*.

Remarks.—This species is usually found in pairs, the cephalic sac of one applied to the posterior part of the posterior sac of another; a disposition from which Hammerschmidt refers it to a new genus under the name of *Clepsidrina*. A very trifling degree of pressure is sufficient to separate them from one another.

Movements.—I never observed any other movement in this *Gregarina* than a slight contractile one, commencing at the anterior part of the posterior sac and proceeding backward.

5. *Gregarina Acheta Abbreviata*.—White, opaque or translucent, with or without a proboscidiform appendage. Cephalic sac orbicular or oval, without any papillary thickening of the integument, or occasionally with an oval proboscidiform prolongation; interior granular mass opaque or translucent.

Posterior sac obconic; granular contents opaque; interior corpuscle transparent. Whole length from the 1-300th to the 1-70th inch; breadth from 1-600th to the 1-130th inch; cephalic sac from 1-1140th inch to the 1-250th inch.

Habitation.—Proventriculus of *Acheta abbreviata*. The same species I have observed in two instances on the exterior of the ventriculus, free within the abdominal cavity.

Movements.—Very slow.

6. *Gregarina Locustae Carolinae*.—Opaque, white, with or without a proboscidiform appendage. Cephalic sac hemispherical, without

papillary thickening of the integument, or occasionally with a pyramidal enlargement or extension anteriorly, terminating in a round or oval proboscidiform prolongation, fringed with delicate, membranous digitations at the free extremity, or with an apparent depression of the parietal integument and a slight conical protrusion of the interior granular mass, which latter is opaque. Partition between the contents of the cephalic and posterior sac very thin. Posterior sac oblong oval or spatulate : posteriorly obtuse ; granular contents opaque ; interior corpuscle transparent, with several nuclear bodies. Whole length from the 1-100th to the 1-60th inch ; breadth from the 1-200th to the 1-120th inch. Cephalic sac from the 1-400th to 1-320th inch long : from the 1-280th inch to the 1-178th inch broad. Corpuscle, in largest, 1-2800th in diameter ; nuclei 1-3500th inch ; nucleoli 1-7000th inch.

Habitation.—Intestine of *Locusta Carolina*.

Movements.—None observed.

7. *Gregarina Blattæ Orientalis*.—Robust, milk-white, opaque. Cephalic sac hemispherical, with a slight papillary thickening of the integument ; contents opaque white. Partition between the cephalic and posterior sac thin. Posterior sac broad ovate, or panduriform, subacute posteriorly : contents opaque, obscuring the interior corpuscle. Whole length average 1-50th inch ; breadth 1-125th inch. Cephalic sac 1-260th inch long ; 1-178th inch broad at the base. Corpuscle 1-275th inch diameter. Muscular striae 1-1000th apart.

Habitation.—Within the intestine, and without closely applied to its parietes, in *Blatta orientalis*.

Movements.—The movements of this species are moderately active.

NOTE.—For further information relative to the Gregarina of Leidy, refer to page 225 and bibliography 599, also to an article by Crawley, Proc. A. N. S., 1903.

On the organization of the genus *Gregarina* of Dufour, Trans. A. P. S., 1853 ; read 1851.

[No. 100. See Bibliography.]

SOME OBSERVATIONS ON NEMATOIDEA IMPERFECTA AND DESCRIPTIONS OF THREE PARASITIC INFUSORIÆ.

1. *Nematoideum cavitatis abdominis Passali cornuti* (pl. 11, figs. 42-45). This worm is found in the abdominal cavity of the *Passalus cornutus*, among the intestines and rete adiposa in about nine-tenths

of the insects. It is met with frequently in great numbers; I have in my collection a vial containing over 5,000, obtained from not more than 40 insects. Sometimes not over half a dozen are found, at others as many as 500 may be discovered in a single insect. The worm is usually curved ventrally, and exhibits but little motion until placed in water, when it becomes quite active, wriggling about for twenty-four hours or more.

It is about $1\frac{1}{2}$ lines long, but varies from 1 to 2 lines, and is about $1-150$ th of an inch wide. The color is white, opaque; occasionally one or two will be found which are more or less brown or even black, but otherwise they do not differ in construction or form.

The form is cylindrical, moderately narrowed toward the extremities; anteriorly truncated, posteriorly rounded, and terminated by a short, acute epidermal spine.

The structure is simple, exhibiting within the integument nothing but an alimentary canal and intervening granular matter.

The integument is thin, strong, elastic, transparent and colorless. It presents a very faint appearance of being finely annulated.

The mouth is round, large, and surrounded by a slight lobed margin or lip.

The pharynx is short, cylindrical, presents several longitudinal striae, and opens into a long, wide, cylindrical oesophagus. The latter is but faintly outlined from the general granular structure of the body. It appears to have several longitudinal folds, and at its commencement has a yellowish colored structure (pl. 11, fig. 45), apparently corneous, composed of oval or oblong lobes placed side by side around the commencement of the oesophagus. The ventricular intestine is white, opaque, cylindrical, a little less than the breadth of the cavity of the body, and in length extending to the anal aperture. Its interior is covered with an epithelial layer, the cells of which are granular, apparently containing oil granules, and measure $1-420$ th of an inch in diameter. The posterior extremity of the ventriculus is rounded, and usually contains a large oblong, translucent, highly refractive mass, of viscid oleo-albuminoid fluid, with several smaller globular masses of the same matter. When the worm is submitted to pressure, a portion of this matter exudes from the anus, with a number of transparent nucleolar and nuclear bodies, but the termination of the ventriculus, or its connection with the anal aperture, is indistinct.

The anus is a short oblique fissure, passing inwards and forwards, upon the ventral surface, a short distance in advance of the posterior extremity of the body. It is bounded by projecting lips, but its

communication with the intestinal canal I could not detect. Posterior to the ventriculus, the body is occupied with a fluid, finely granular, and a coarsely granular oil-like matter. The remainder of the interval of the body is filled with fluid and faintly granular matter.

Measurements.—Length, 1 to 2 lines; breadth at mouth, 1-600th inch; breadth at commencement of ventriculus, 1-280th inch; greatest breadth about middle, 1-150th inch; breadth just in advance of anus, 1-250th inch. Length of caudal spine, 1-2500th inch; from base of spine to anus, 1-300th inch; breadth of ventriculus at commencement, 1-320th inch; breadth of ventriculus at middle, 1-214th inch; breadth of ventriculus at termination, 1-280th inch.

This entozoon I have seen in hundreds of the *Passalus*, at all seasons of the year, but in none did I ever discover it in any other stage of development than the one just described.

From the frequency and great numbers in which it is found, I thought it would afford an excellent opportunity to try the experiment, if, upon introduction into another animal, it would undergo any progress in its development. I accordingly obtained from the forests in our neighborhood, and through my friend Baird from the forests near Carlisle, over 200 individuals of *Passalus cornutus*. A dozen of them I opened, and found them all infested with great numbers of the entozoon just described, and I therefore naturally concluded from this fact, in addition to past experience, that most or probably all the other insects contained the same. Having obtained a dozen large frogs (*Rana pipiens*), after keeping them two weeks until they had voided all indigesta from the alimentary canal, I killed eight of them, and examined them closely for entozoa. In seven I found in the lungs *Distomum variegatum*: in all, *Distomum cygnoides* in the bladder; none in the intestines; and in five an imperfect stage of a species of *Filaria* beneath the mucous coat of the stomach, in the mesentery, and in the abdominal muscles.

The remaining four frogs I then fed daily upon 10 individuals of *Passalus cornutus* each for four days in succession, so that each frog in that time took 40 insects, in all 160. It is not to be presumed that the frogs voluntarily took this prescribed fare, for I was under the necessity of cutting off the legs, elytra, and mouth organs of the insects, and then forcing them into the throat of the frogs.

In twenty-four hours after taking the first involuntary dose of insect food the frogs commenced voiding the indigestible parchmentaceous segments of the skeleton of the insects per anum, which they

continued for a week after the unusual mode of administering their food was stopped.

At the end of two weeks from the commencement of feeding the frogs I killed one of them, and carefully examined the intestinal canal and other organs for the *Nematoideum*, Passali, but not a trace of it was to be found. The cloaca yet contained one or two fragments of the skeleton of the *Passalus*, with some epithelial scales, mucus, and a dark, mud-like, granular matter, but nothing else. The entozoon had been digested with the soft parts of the insect. Two days after I killed the remaining frogs, but in none did I discover the slightest trace of the entozoon in question. From the results thus obtained we may conclude that this parasite finds no condition favorable to its existence, leaving out of the question entirely any farther development, in frogs, or probably in any reptile. But still the entozoon may pass part of its existence in other animals. In a state of nature frogs would rarely have a chance of feasting upon *Pussatus* (the habitation of *Pussatus*, however, offers no reason why a frog should not occasionally feast upon them). At one time I thought the insect was confined to the haunts in which it is usually found, but it undoubtedly flies at night, as I have found it in places where some days before they did not exist, and my late friend, Dr. Benj. Kern, once brought me half a pint of this insect, which he obtained on the Atlantic ocean a few miles from shore, with numerous other insects, one morning after there had been a brisk wind in the night), because the latter is found in forests, beneath bark and in the wood of decaying dead trees, and here the woodpecker (*Picus*), or other insectivorous birds, would be most likely to meet with it, and with such birds a similar experiment to the one performed with frogs might be tried to see if the development of the entozoon would not advance within them.

2. *Nematoideum thoracis cavitalis Passali cornuti* (pl. 11, Fig. 46).—This is an anguillula-like worm in an imperfect condition, found occasionally in the cavity of the thorax of *Passalus cornutus*. It resembles an embryonic *Ascaris*. Its movements are active and wriggling. It is whitish, translucent, cylindrical, and attenuated and acute posteriorly.

Structure.—Integument transparent and colorless. Oesophagus long, narrow, cylindrical, and faintly outlined. Intestine broad, cylindrical, granular in appearance, and faintly outlined. Anus an oblique fissure, not very distinct, just in advance of the tail, which latter is short and acute. Length 1-66th inch; breadth 1-100th inch.

3. *Nematoideum intestinalis Armadillonis pellucens* (pl. 11, Fig. 47).—This is also an anguillula-like entozoon, found coiled up and adhering by the mouth to the epithelial layer of the intestine of *Armadillo pellucens*. It is white, cylindrical, attenuated, and acute posteriorly. The intestinal canal presents the same appearance as in the last, but the oesophagus is broader. Length 1-53d inch; breadth 1-360th inch.

4. *Nematoideum integumenti Lumbriculi limosus* (pl. 11, Fig. 48).—This is a small entozoon which I found, six in number, doubled up and motionless, contained in transparent oval cysts, imbedded in the integument of the 9th, 11th, and 15th annuli of a *Lumbriculus limosus*. It resembled an embryo within an ovum. Its form is cylindrical, subacute posteriorly, truncated anteriorly, colorless, and transparent. No interior organs were observable, except a small, round, transparent corpuscle posteriorly, and anteriorly a proboscisidiform body, partly projecting from the anterior extremity. Length 1-560th of an inch.

SMITHSONIAN MISCELLANEOUS COLLECTIONS

PART OF VOLUME XLVI

INDEX TO THE LITERATURE

OF

GALLIUM

1874-1903

PREPARED BY

PHILIP E. BROWNING, PH. D.

(No. 1543)

CITY OF WASHINGTON
PUBLISHED BY THE SMITHSONIAN INSTITUTION

1904

WASHINGTON, D. C.
PRESS OF JUDD & DETWEILER
1904

LETTER OF TRANSMITTAL.

WASHINGTON AND LEE UNIVERSITY,

DEPARTMENT OF CHEMISTRY,

LEXINGTON, VA., October 18, 1904.

The Committee of the American Association for the Advancement of Science having charge of Indexing Chemical Literature has voted to recommend to the Smithsonian Institution for publication the following:

INDEX TO THE LITERATURE OF GALLIUM, 1875-1903;

INDEX TO THE LITERATURE OF GERMANIUM, 1886-1903;

both prepared by Philip E. Browning, Ph. D., of the Kent Chemical Laboratory of Yale University.

JAMES LEWIS HOWE,

Chairman.

Mr. S. P. LANGLEY,

Secretary of the Smithsonian Institution.

This publication forms one of the following series:

Index to the Literature of Uranium, 1785-1885, by Henry Carrington Bolton, 1885.

Index to the Literature of Columbium, 1801-1887, by Frank W. Traphagen, 1888.

Index to the Literature of the Spectroscope, by Alfred Tuckerman, 1888, 1902.

Index to the Literature of Thermodynamics, by Alfred Tuckerman, 1890.

A Bibliography of the Chemical Influence of Light, by Alfred Tuckerman, 1891.

A Bibliography of Aceto-Acetic Ester, by Paul H. Seymour, 1894.

Index to the Literature of Didymium, 1842-1893, by A. C. Langmuir, 1895.

Indexes to the Literature of Cerium and Lanthanum, by W. H. Magee, 1895.

A Bibliography of the Metals of the Platinum Group, by Jas. Lewis Howe, 1897.

Review and Bibliography of the Metallic Carbides, by J. A. Mathews, 1898.

Index to the Literature of Thallium, 1861-1897, by Miss Martha Doan, 1898.

Index to the Literature of Zirconium, by A. C. Langmuir and Charles Baskerville, 1899.

A Bibliography of the Analytical Chemistry of Manganese, 1785-1900, by Henry P. Talbot and John W. Brown, 1902.

Index to the Literature of Thorium, 1817-1902, by Cavalier H. Joüet, 1903.

INDEX TO THE LITERATURE OF GALLIUM.

(1875-1903.)

PREPARED BY PHILIP E. BROWNING.

1875: (1). LECOQ DE BOISBAUDRAN. (Discovery.)

Compt. rend., lxxxii, 493; Ber. viii, 1355, 1680; Ztschr. Anal. Chem., xvi, 239; Bull. Soc. Chim. (Paris), n. f., xxiv, 370; Amer. J. Sci., (3), xi, 320; Jsb. (1875), 205; Pogg. SMITHSONIAN MISCELLANEOUS COLLECTIONS

PART OF VOLUME XLVI

—
INDEX TO THE LITERATURE

OF

GERMANIUM

1886-1903

PREPARED BY

PHILIP E. BROWNING, PH. D.

(No. 1544)

CITY OF WASHINGTON
PUBLISHED BY THE SMITHSONIAN INSTITUTION

1904

WASHINGTON, D. C.
PRESS OF JUDD & DETWEILER
1904

LETTER OF TRANSMITTAL.

WASHINGTON AND LEE UNIVERSITY,
DEPARTMENT OF CHEMISTRY,

LEXINGTON, VA., *October 18, 1904.*

The Committee of the American Association for the Advancement of Science having charge of Indexing Chemical Literature has voted to recommend to the Smithsonian Institution for publication the following:

INDEX TO THE LITERATURE OF GALLIUM, 1875-1903;

INDEX TO THE LITERATURE OF GERMANIUM, 1886-1903;

both prepared by Philip E. Browning, Ph. D., of the Kent Chemical Laboratory of Yale University.

JAS. LEWIS HOWE,
Chairman.

Mr. S. P. LANGLEY,

Secretary of the Smithsonian Institution.

This publication forms one of the following series:

Index to the Literature of Uranium, 1785-1885, by Henry Carrington Bolton, 1885.

Index to the Literature of Columbium, 1801-1887, by Frank W. Traphagen, 1888.

Index to the Literature of the Spectroscope, by Alfred Tuckerman, 1888, 1902.

Index to the Literature of Thermodynamics, by Alfred Tuckerman, 1890.

A Bibliography of the Chemical Influence of Light, by Alfred Tuckerman, 1891.

A Bibliography of Aceto-Acetic Ester, by Paul H. Seymour, 1894.

Index to the Literature of Didymium, 1842-1893, by A. C. Langmuir, 1895.

Indexes to the Literature of Cerium and Lanthanum, by W. H. Magee, 1895.

A Bibliography of the Metals of the Platinum Group, by Jas. Lewis Howe, 1897.

Review and Bibliography of the Metallic Carbides, by J. A. Mathews, 1898.

Index to the Literature of Thallium, 1861-1897, by Miss Martha Doan, 1898.

Index to the Literature of Zirconium, by A. C. Langmuir and Charles Baskerville, 1899.

A Bibliography of the Analytical Chemistry of Manganese, 1785-1900, by Henry P. Talbot and John W. Brown, 1902.

Index to the Literature of Thorium, 1817-1902, by Cavalier H. Jouët, 1903.

INDEX TO THE LITERATURE OF GERMANIUM.

(1886-1903.)

PREPARED BY PHILIP E. BROWNING.

SMITHSONIAN MISCELLANEOUS COLLECTIONS

PART OF VOLUME XLVI

INDEX TO THE LITERATURE

OF

INDIUM

1863-1903

PREPARED BY

PHILIP E. BROWNING, PH. D.
of the Kent Chemical Laboratory of Yale University

(No. 1571)

CITY OF WASHINGTON
PUBLISHED BY THE SMITHSONIAN INSTITUTION
1905

WASHINGTON, D. C.
PRESS OF JUDD & DETWEILER (INC.)
1905

LETTER OF TRANSMITTAL.

WASHINGTON AND LEE UNIVERSITY,
DEPARTMENT OF CHEMISTRY,
LEXINGTON, Va., March 25, 1905.

The Committee of the American Association for the Advancement of Science having charge of Indexing Chemical Literature has voted to recommend to the Smithsonian Institution for publication the following:

INDEX TO THE LITERATURE OF INDIUM, 1863-1903;

prepared by Philip E. Browning, Ph. D., of the Kent Chemical Laboratory of Yale University.

JAS. LEWIS HOWE,
Chairman.

Mr. S. P. LANGLEY,

Secretary of the Smithsonian Institution, Washington.

This publication forms one of the following series:

- Index to the Literature of Uranium, 1785-1885, by Henry Carrington Bolton, 1885.
- Index to the Literature of Columbium, 1801-1887, by Frank W. Traphagen, 1888.
- Index to the Literature of the Spectroscope, by Alfred Tuckerman, 1888, 1902.
- Index to the Literature of Thermodynamics, by Alfred Tuckerman, 1890.
- A Bibliography of the Chemical Influence of Light, by Alfred Tuckerman, 1891.
- A Bibliography of Aceto-Acetic Ester, by Paul H. Seymour, 1894.
- Index to the Literature of Didymium, 1842-1893, by A. C. Langmuir, 1895.
- Indexes to the Literature of Cerium and Lanthanum, by W. H. Magee, 1895.
- A Bibliography of the Metals of the Platinum Group, by Jas. Lewis Howe, 1897.
- Review and Bibliography of the Metallic Carbides, by J. A. Mathews, 1898.
- Index to the Literature of Thallium, 1861-1897, by Miss Martha Doan, 1898.
- Index to the Literature of Zirconium, by A. C. Langmuir and Charles Baskerville, 1899.
- A Bibliography of the Analytical Chemistry of Manganese, 1785-1900, by Henry P. Talbot and John W. Brown, 1902.
- Index to the Literature of Thorium, 1817-1902, by Cavalier H. Joüet, 1903.
- Index to the Literature of Gallium, 1875-1903, by Philip E. Browning, 1904.
- Index to the Literature of Germanium, 1886-1903, by Philip E. Browning, 1904.

INDEX TO THE LITERATURE OF INDIUM.

(1863-1903.)

PREPARED BY PHILIP E. BROWNING.

Chem. News, xxviii, 28; Am. Chemist (1873), iii, 242; J. Chem. Soc. (Lond.), xxvii, 34; Jsb. (1873), 275.
- 1873: (2). ROESSLER. (Reactions.)
J. prakt. Chem. (N. F.), vii, 14; Chem. News, xxviii, 227; Jsb. (1873), 275; Bull. Soc. Chim., xx, 170; J. Chem. Soc. (Lond.), xxvii, 846; Tidsskrift, [1], xii, 175; N. Arch. Ph. Nat., xlvi, 238.
- 1874: (1). SCHNEIDER. (Double sulphides.)
Pogg. Ann. (Jubel) (1874), 158, 163; Bull. Soc. Chim., xxii, 158; J. prakt. Chem., ix, 209.

- 1874: (2). TANNER. (Occurrence.)
Chem. News, xxx, 141; Jsb. (1874), 1227; J. Chem. Soc. (Lond.), xxvii, 1144; Chem. Centrbl. (1874), 647.
- 1875: (1). NILSON. (Valence.)
Ber., viii, 658; ix, 1059.
- 1875: (2). NILSON. (Selenite.)
Bull. Soc. Chim., xxiii, 497.
- 1875: (3). —— (Value.)
Min. and Scient. Press; Berg. u. Hütten. Ztg., xxxiv, 244; Chem. Centrbl. (1875), 544.
- 1876: (1). NILSON. (Platinum salts.)
Ber., ix, 1727, 1056, 1142; Jsb. (1876), 293; Bull. Soc. Chim., xxvii, 209, 246.
- 1876: (2). CLAYDEN and HEYCOCK. (Spectrum.)
Phil. Mag., (5) ii, 387; Amer. J. Sci., (3) xiii, 57; Jsb. (1876), 144; (1877), 1034; Ztsch. anal. Chem. (1877), 95; Chem. Centrbl. (1877), 2, 689.
- 1876: (3). LECOQ DE BOISBAUDRAN. (Reactions.)
Ber., ix, 1807.
- 1876: (4). DELACHANEL and MERMET. (Occurrence in zinc.)
Bull. Soc. Chim. (Paris), N. F., xxv, 197; Chem. Centrbl. (1876), 339.
- 1877: (1). AEWORTH and ARMSTRONG. (Action of nitric acid.)
J. Chem. Soc. (Lond.), xxii, 84.
- 1877: (2). LECOQ DE BOISBAUDRAN. (Non-volatility.)
Ber., x, 92.
- 1877: (3). FLIGHT. (Occurrence at Durham.)
Ber., x, 2054.
- 1877: (4). —— (Value.)
Berg. u. Hütten. Ztg., xxxv, 410; Chem. Centrbl. (1877), 160.
- 1878: (1). CORNWALL. (Occurrence in American blendes.)
Amer. Chemist, viii, 339; Jsb. (1878), 253.
- 1878: (2). LIVEING and DEWAR. (Spectrum.)
Proc. Roy. Soc. (Lond.), xxvii, 132, 350, 494; Jsb. (1878), 182.
- 1878: (3). DE NEGRI. (Occurrence in calamine.)
Gazz. Chim. Ital., viii, 120; Ber., xi, 1249; Jsb. (1878), 284; Wag. Jsb., xxiv, 11; J. Chem. Soc. (Lond.), xxxiv, 708.

- 1878: (4). LOCKYER. (Occurrence in the sun.)
Proc. Roy. Soc. (Lond.), xxvii, 279; C. R., lxxxvi, 317; Jsb. (1878), 185.
- 1879: (1). MEYER. (Density of the chloride.)
Ber., xii, 611; Amer. Chem. J., i, 213; J. Chem. Soc. (Lond.), xxxvi, 379; Amer. J. Sci., (3), xviii, 71; Bull. Soc. Chim., xxxiii, 113; Tidsskrift, (1), xviii, 260.
- 1879: (2). LOCKYER. (Heating of the metal in vacuo.)
Chem. News, xi, 101; C. R., lxxxix, 514; Jsb. (1879), 176.
- 1879: (3). JUNGFLEISCH. (Separation from blendes.)
Bull. Soc. Chim., xxxi, 50; Chem. Centrbl. (1879), 234.
- 1880: (1). NIJSSON and PLITTERSSON. (Physical constants of oxide and sulphate.)
Ber., xiii, 1459; Jsb. (1880), 237; C. R., xc, 232.
- 1880: (2). SCHUCHT. (Electrolysis of salts)
Chem. Ztg. (1880), 292; Berg. u. Hütten. Ztg., xxxix, 121; Jsb. (1880), 174, 1143; Chem. Centrbl. (1880), 374; Wag. Jsb., xxvi, 412.
